From: Bill K0ZL
Topic: 6262 Message: 6265

Hi again, Kevin! Happy New Year.

The 930 was the first all-solid-state, contest quality radio that Kenwood put out. It was in the same time arena as the TS-430.

It uses 29volt finals and drivers, the latter of which are getting rare and expensive. The AVR (power supply regulator) unit is another weak point, and it's rare to find a 930 that is relatively unscathed in that area. For these reasons I don't recommend the 930 even as a backup.

The 940 is a better choice; the AVR unit is easier to get to, and the circuit boards are much easier to remove and replace should the need arise. But again, it's hard to find one in near-mint condition these days; I would not buy one in any other condition than near-mint.

I would recommend that you look at a 12v radio as a backup, simply because we all need some capability to operate off batteries should the need arise. Take a look at the TS-430, or if you want a big format rig, look at the TS-850S. These are both quite repairable and parts are by and large still available.

If you find a TS-440SAT that is in really good shape and does not have the all-dots syndrome, that is also a good buy for the shack.

What are the symptoms of blown finals?
When I tuned up my 520 this afternoon, got all the readings according to the manual OK. Except when I had the meter in RF reading I saw no response, but my antenna tuner meter said I was putting out. Afraid to keep it going in that manner so switched off. This was with both a dummy load and my random length wire (out in the rain).
Should I look for problem in the meter switch, ignore the problem???
This was on CW mode.

The sensitivity of the RF reading is adjustable via the RF voltage control on the side of the 520. See Section 3 of the operating manual.

John,

I apologise for mentioning what may be obvious, but sometimes things are only obvious with hindsight. Check that the narrow/wide filter button isn't in the narrow position. On SSB, if you don't have the narrow SSB filter fitted, then the IF path is open and the only signal feed-through is via the capacitance of the filter switching diodes. On my 530S, the calibration signal can be just heard down in the noise with the switch in the narrow position and SSB selected. You might also hear a local station, but the front end may then be overloaded hence the poor audio.

If you do not have a CW filter fitted then you will have the same symptoms on CW.

A failed filter switching diode is another possibility, or the filter switching voltage not getting to this part of the circuit.

Hello Ken

i wanted to thank you for the mic wiring for the shure 444 to my 950.
maybe you can tell me if there is a better mic for this rig i have now tried a Heil pr-20 and people said its ok nothing great and the 444 they say is not at all good real weak audio reports.i was wondering if you might have any suggestions a couple operators said a D-104 but i heard they dont work well with kenwoods.

thanks and 73s
Tim

Ken Winterling <wa2lbi@...> wrote:
Tim,

Here is the 444 data sheet:
http://www.shure.com/pdf/discontinued/444.pdf

Here is the Kenwood 8 pin mic jack wiring (this info should be in the '950SD manual):
1- mic hi
2- PTT
3- frequency down
4- frequency up
5- +8VDC
6- n/c
7- mic lo (shield)
8- PTT ground

If your your 444 has the original factory 2 conductor cable with a black and white wire inside the shield then the black wire is the mic hi and the white wire is for PTT. The shield is common to both. If that is the case you would wire the connector as follows:

Mic black wire (mic hi) to Kenwood plug pin 1 (mic hi)
Mic white wire (PTT) to Kenwood plug pin 2 (PTT)
Mic shield (mic lo and PTT ground) to Kenwood plug pins 7 (mic lo) and 8 (PTT ground)

While you are at it you should remove the factory jumper inside the base of the 444 that shorts the mic element when the PTT bar is released (up). With the jumper in place you need to flip the VOX switch under the mic AND depress/lock the PTT bar to use VOX. If you remove the jumper you can leave the switch in the normal/PTT position and use VOX without moving the switch or the PTT bar. This also gives you the ability to over ride the VOX with the PTT if necessary.

Good luck. Let me know if I can be of further assistance.

What kind of audio are you looking to achieve, Tim?

The PR 20 should provide some nice sound. A Heil gold line would be a good performer as well. The PR-20 may require some outboard processing.

An amplified D-104 may overdrive it. The D-104 has a response curve very similar to the Heil Gold Line. They have always sounded good on the right radio.

If you are looking for wide audio, the 950 may have some limitations.

Looking for Hi-Fi type audio? There is a group just for that and they will answer all Q's about the TS-950 and Hi-Fi.

From: Ken Winterling
Topic: 6249 Message: 6271

Tim,

You are correct, the Astatic D-104 would not be a good choice. It needs to "see" a much higher impedance than the TS-950 presents. It will not sound very good.

I have never used a Heil mic so I can't offer any personal comments but many folks are using them. The Shure 444 is known as a decent mic. Have you tried it on other rigs and/or had another operator use it? Maybe the mic element is defective and/or your voice characteristics are not compatible with the frequency response of the mic. Some guys sound better on one mic compared to another. Does the '950 have any transmit audio tailoring? If so, did you try making any adjustments while speaking with another station?

I don't own a '950 but on my TS-940SAT I have used all of the following mics and have not received negative reports (that doesn't mean the audio was good, just that nobody complained!). They are listed in no particular order. I do not use any audio gear between the mic and the radio.

Astatic 10-DA
Astatic DN-500
Electro-Voice 664
Shure 404B (hand mic)
Shure 404C (hand mic)
Shure 444D
Shure 520SL
Kenwood MC-60

I'm sure there are TS-950s* users on this list who would be of more assistance as they could give you specifics on their stations.

Good luck & 73,

Ken, WA2LBI

From: P. Coppin
Topic: 6249 Message: 6272

I have a TS-940. I use it from 1994.

My voice has too many low tones and Shure444 has good sound but not so good for my voice during DX calls. For several years a tested lots of microphones: Shure444, MC-60, HC4 Heil Sound key element and HC5 key element. After long time tests I have chosen the HC5 element - I mounted it inside a MC-50 body. I love the 444 body so I use it with a Yaesu FT-902 mic cartridge (GREAT sound) connected to that rig.

There is a pot in the back of the rig, for the RF
meter setting. Simply rotating it back and forth
should bring the reading back. They do get dirty.

Bert is right; the 520 adjustment is on the left side.
530-820-830 is on the back panel, upper left, as you
face the back of the rig.

From: Bill K0ZL
Topic: 6249 Message: 6275

Tim, the MC-50 and MC-60 work very well; the 50 will
require an 8 pin plug, it usually comes with a 4 pin.

I use an Astatic 10DA mic on my 850 and get very good
audio reports. That is the chrome bullet head mic that
also fits on the UG-8 stand. Generally you want to use
the 10DA for SSB and the D104 for AM work with the
older boat anchor rigs. The D104 to me sounds too
tinny for either however.

HV filter cap gone; Beauty of this design is that one
cap goes bad, no sparks flames or blown fuses; you
just loose half your plate voltage!

Digikey P7453-ND, get two for you and two for a
friend.

They are much shorter than the original, but same
diameter so they will fit the clamps.

6280. 400 TO 500 VOLTS.....BUT

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-03 21:29:09 UTC
From: Bob
Topic: 6280 Message: 6280

But the thing is , when I turn on the 830 (heaters off) , I have 700 volts THEN when I put the heater switch on , with in 15 seconds or so it will slowly drop to 475 volts and stay there. Then if I turn the heater switch back off.....another 15 seconds it slowly goes back up to 700 volts....is one cap just breaking down with voltage?
Thanks for the help fellas.....BOB

6281. 820 ALC Meter Reading

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-03 22:35:47 UTC
From: Bill Hall
Topic: 6281 Message: 6281

Have no ALC meter reading on tune up or transmit. Also no "S" meter reading during receive.All other meter functions OK.
Tune up on 21 MHz readings as follows:
Bais- 60 ma
Plate Tuning- OK
IP- 250 ma peak
HV- 825 volts
Adjusted the drive by signal strength. Transmitter produces 98 W.

Any help will be appreciated.

You have a cap with real high ESR or "plate
resistance" due to breakdown of the electrolytic
solution. It's still a cap, but with insufficient
capacity to keep the voltage doubler circuit from
working properly under load.

From: Bill K0ZL
Topic: 6281 Message: 6283

It could just need an alignment of the RF stages for
each band. Check it on 80 meters into a dummy load.

As for the S meter, make sure that the AGC switch is
set to SLOW or FAST, not OFF, if your 820 has that
switch position.

I wouldn't worry about it too much. The worst that could happen is that you will blow the transformer and/or burn the house down.

Some caps will handle twice their rating others will not handle 90% of their rating. One of two things will happen.

1. You will live happily ever after.
2. You will hear a loud pop and smell smoke.

Be sure that you have the right fuse installed.
Placing a 10 ohm 1/2 watt resistor in series with the transformer HV windings is not a bad idea.
Usually, if the caps or rectifiers shorts the resistors will open saving the transformer. In the mean time, look for better rated caps.

Oh, BTW, don't leave it on when you are not at home or asleep.

Good DX,
Vy 73, Walt N9WB
Good audio is an Amateur Radio tradition, not a crime.

They should be OK until you get the right ones in.
Just make sure your line fuse is right 5 amp fast blow
or AGC-5

I had the YD-844, it is a great mike but I sold it because it has low stand
so I had to bend over it, the Shure 444 is higher. Moreover the original
FT-101 hand microphone had a little bit louder audio than YD-844 therefore I
put that handy mic cartridge in my 444 so I have a GREAT cartridge in a
GREAT extendable microphone body for my FT-902DM.

From: P. Coppin
Topic: 6249 Message: 6289

Did you hear about this modification ??

About 20 years ago several dxer suggested to cover the sides holes of mc-50
and 60 with rubber or scotch tape to have a higher audio quality (probably
to cut the room noise).

I did it on both microphones. They sound good.

I have sent a picture of my shack to the group's album.

6290. Re: [TS-520_820_530_830] as for MC-50 and MC-60

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-05 14:42:36 UTC
From: Walt Breining
Topic: 6249 Message: 6290

That is an olde trick. Actually, the MC-50 mike elements were lacking in articulation. Covering the side holes with scotch tape, electrical tape, rubber, or a toilet paper
tube puts back pressure on the element making it more middy and adding articulation.

The best way I found was to remove the top cover. On the sides of the element there is nylon cloth or sometimes felt. Putting one layer of masking tape over this material will increase back pressure. Use two pieces, one on each side between the wire connections. I found that if one on one side is about 1/4 inch short to not fully cover that side it is a bit better. Masking tape lets just the right amount of air still pass. Be careful.

The MC-60 has many other issues. Most of these mikes had the hot audio and the ground reversed inside the mike itself resulting in RF and response problems. These are detailed in the files section of KenwoodMics Yahoo group.

Now some history if I may reminiscence:

Many people think that if they purchase the factory matching mike they will get great sound. Actually during the 70's and somewhat today, this was not the case.
The manufactures would purchase generic elements and tailor a mike to cosmetically match
their gear. The mike was not necessary optimum electrically.
Another problem was that these mikes were designed by people who spoke Japanese.

In those days, lines of communications between the Japanese manufactures and American users was poor. The Japanese language uses many vowels, the a,e,i,o,u sounds. The American language uses more consonants, the c,k,s,t, sounds. Mikes tailored for Japanese users did not work well
for English speaking Americans. They muffled the English language.

The MC-50 uses a sound reinforcement element that is good for Paging applications and for the South East Asian languages. It is the same element that is some models of the muddy Diesel CB noise canceling mike with the screen front sold at truck stops.

In the mid 70's a group of us used to operate on 7240 late nights and started wondering why some
rigs and mikes sounded clearer and had more punch than others. Among the many was Bob Heil, K9EID. Bob, like myself always liked the TS-820. Bob built custom audio mixers for performers. We started using various circuits to enhance our audio including series capacitors, compressors, and

mechanical modifications such as the one above. We then started trying different mike elements in our MC-50s. Heil located a source of a square ceramic element that sounded much better than the MC-50 element. He called it the Heil HC-1, Heil ceramic 1.

Over the next couple of years, Heil did a lot of research and had the manufacture of these elements to custom make elements to his audio response specifications. So along came the HC-2 and the HC-3.

Finally he settled on the HC-4 and HC-5. The HC-4 was a element meant to be punchy with extreme mids but not natural sounding. It was for busting DX pile ups. The HC-5 was a more full dynamic element in the same package but had a subtle rise in the presence area to increase articulation. The HC-5 worked good in the MC-50.

Bob then built the EQ-100 which was based on the various active EQ projects that we were doing on 7240. He published this as a project in QST. This was followed by the EQ-200.

At Dayton engineers from Icom, Yaesu, and Kenwood attended his audio forums and the result was greatly improved sound of the Asian made rigs. Imagine how cool it was to have engineers from the major Amateur Radio manufactures come to your forum to learn how to make their gear better!

Bob started making mikes using the HC elements and perfected the enclosure design to enhance his elements. The enclosure has a lot to do with the sound.

Heil later contracted the manufacture of some dynamic elements that were physically more typical of normal dynamic elements but still had boosted articulation. Heil started marketing headsets that the broadcast sports industry picked up on. They typically used the HC-5 element.

Dynamic elements had not changed much for over 20 years, until the last couple of years.
Then Heil, with the help of Joe Walsh, and a guy that has an outstanding tool shop along with others came up with a new Dynamic design that used low mass (light weight) wire and a quilted element, among other features found in the $1000 mikes such as a hum bucking coil. Heil incorporated these new elements in his Pro 20, 30, and 40 as well as in his Classic microphone series.

The Pro 40 is really getting noticed by the broadcast industry. One of those now replaces the 77 DX on David Letterman's desk. It has many of the qualities of a condenser mike but does not require phantom power and does not pop and hiss as bad as condensers do.

As Bob says, "It all starts with the microphone." All of this started with efforts to improve the MC-50 microphone using tape and toilet paper tubes!

Now some notes:

BTW, ESSB (enhanced single side band) is not new. It started on 7240 in the mid 70's.

K0ZL pointed out that elements from microphones used with tape and cassette recorders made before the use of electret elements are often good sounding replacements in Kenwood mikes.

Please note that we have a Yahoo forum connected with this one called KenwoodMics. We probably should be discussing a lot of these mike issues there.

Want a Pro 40? The Fox Tango yahoo group is raffling off a Heil Pro-40 and a H.F. mobile rig.

From: P. Coppin
Topic: 6249 Message: 6291

Let me thank you Walt. I have appreciated very much your email.

Probably you remember the first article on CQ Magazine about the HC4 and HC5 elements.

Bob Heil was right. I appreciated very much his study.

After that CQ issue I bought immediately the HC-4 element. Then I got the HC-5 for wider range response.

I still use it with my TS-940.

Thanks Walt

Paul i8ixo

Oggetto: [POSSIBILE SPAM]Re: [TS-520_820_530_830] as for MC-50 and MC-60

That is an olde trick. Actually, the MC-50 mike elements were lacking in articulation. Covering the side holes with scotch tape, electrical tape, rubber, or a toilet paper
tube puts back pressure on the element making it more middy and adding articulation.

The best way I found was to remove the top cover. On the sides of the element there is nylon cloth or sometimes felt. Putting one layer of masking tape over this material will increase back pressure. Use two pieces, one on each side between the wire connections. I found that if one on one side is about 1/4 inch short to not fully cover that side it is a bit better. Masking tape lets just the right amount of air still pass. Be careful.

The MC-60 has many other issues. Most of these mikes had the hot audio and the ground reversed inside the mike itself resulting in RF and response problems. These are detailed in the files section of KenwoodMics Yahoo group.

Now some history if I may reminiscence:

I've used a toilet paper roll(without the toilet paper) on my MC-50 for years. Gives you that added punch when conditions were poor or when working in a contest, and you didn't care your audio was restricted to telephone style audio.

6293. ts-830s

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-05 21:17:24 UTC
From: wb4mnk
Topic: 6293 Message: 6293

We have a TS-830S and the output would fall off to around 80 watts on 20 meters from around 105 watts so we order some new GE/JAN 6146W's and a new 12by7a driver. I installed the tubes today and turn the rig on and let warm up some and then turned the heater switch on and was going to let the tubes warm up for maybe 20 minutes before I would try and load the rig up on 20 meters. Band switch was set for 20 meters and the mode switch was in usb. Well maybe into warming up for around one minute the rig acted like something shorted out twice and we turn it off. WE replaced the new 6146W tubes with the old 6146W tubes and now when we checked the idle current it goes full scale. I pulled the final unit and checked r2-r5 which are 20ohm resistors. They all check installed in the board at 42.9ohms. Could someone please direct me into the correct area to check and help me get this rig back on the air. Thanks

Bert is right; the 520 adjustment is on the left side.
530-820-830 is on the back panel, upper left, as you
face the back of the rig.

That is an olde trick. Actually, the MC-50 mike elements were lacking in
articulation. Covering the side holes with scotch tape, electrical tape, rubber, or a toilet paper
tube puts back pressure on the element making it more middy and adding articulation.

The best way I found was to remove the top cover. On the sides of the element there is nylon cloth or sometimes felt. Putting one layer of masking tape over this material will increase back pressure. Use two pieces,
one on each side between the wire connections. I found that if one on one
side is about 1/4 inch short to not fully cover that side it is a bit better. Masking tape lets just the right amount of air still pass. Be careful.

The MC-60 has many other issues. Most of these mikes had the hot audio and
the ground reversed inside the mike itself resulting in RF and response problems. These are detailed in the files section of KenwoodMics Yahoo group.

Now some history if I may reminiscence:

Many people think that if they purchase the factory matching mike they will
get great sound. Actually during the 70's and somewhat today, this was not
the case.
The manufactures would purchase generic elements and tailor a mike to

cosmetically match
their gear. The mike was not necessary optimum electrically.
Another problem was that these mikes were designed by people who spoke
Japanese.

In those days, lines of communications between the Japanese manufactures
and
American users was poor. The Japanese language uses many vowels, the
a,e,i,o,u sounds. The American language uses more consonants, the
c,k,s,t,
sounds. Mikes tailored for Japanese users did not work well
for English speaking Americans. They muffled the English language.

The MC-50 uses a sound reinforcement element that is good for Paging
applications and for the South East Asian languages. It is the same
element
that is some models of the muddy Diesel CB noise canceling mike with the
screen front sold at truck stops.

In the mid 70's a group of us used to operate on 7240 late nights and
started wondering why some
rigs and mikes sounded clearer and had more punch than others. Among the
many was Bob Heil, K9EID. Bob, like myself always liked the TS-820. Bob
built custom audio mixers for performers. We started using various
circuits
to enhance our audio including series capacitors, compressors, and
mechanical modifications such as the one above. We then started trying
different mike elements in our MC-50s. Heil located a source of a
square
ceramic element that sounded much better than the MC-50 element. He
called
it the Heil HC-1, Heil ceramic 1.

Over the next couple of years, Heil did a lot of research and had the
manufacture of these elements to custom make elements to his audio
response
specifications. So along came the HC-2 and the HC-3.

Finally he settled on the HC-4 and HC-5. The HC-4 was a element meant
to be
punchy with extreme mids but not natural sounding. It was for busting DX
pile ups. The HC-5 was a more full dynamic element in the same package
but
had a subtle rise in the presence area to increase articulation. The
HC-5
worked good in the MC-50.

Bob then built the EQ-100 which was based on the various active EQ
projects
that we were doing on 7240. He published this as a project in QST. This
was
followed by the EQ-200.

At Dayton engineers from Icom, Yaesu, and Kenwood attended his audio forums
and the result was greatly improved sound of the Asian made rigs. Imagine
how cool it was to have engineers from the major Amateur Radio manufactures
come to your forum to learn how to make their gear better!

Bob started making mikes using the HC elements and perfected the enclosure
design to enhance his elements. The enclosure has a lot to do with the
sound.

Heil later contracted the manufacture of some dynamic elements that were physically more typical of normal dynamic elements but still had boosted articulation. Heil started marketing headsets that the broadcast sports industry picked up on. They typically used the HC-5 element.

Dynamic elements had not changed much for over 20 years, until the last couple of years.
Then Heil, with the help of Joe Walsh, and a guy that has an outstanding tool shop along with others came up with a new Dynamic design that used low
mass (light weight) wire and a quilted element, among other features found
in the $1000 mikes such as a hum bucking coil. Heil incorporated these new
elements in his Pro 20, 30, and 40 as well as in his Classic microphone series.

The Pro 40 is really getting noticed by the broadcast industry. One of those now replaces the 77 DX on David Letterman's desk. It has many of the
qualities of a condenser mike but does not require phantom power and does
not pop and hiss as bad as condensers do.

As Bob says, "It all starts with the microphone." All of this started with
efforts to improve the MC-50 microphone using tape and toilet paper tubes!

Now some notes:

BTW, ESSB (enhanced single side band) is not new. It started on 7240 in the
mid 70's.

K0ZL pointed out that elements from microphones used with tape and cassette
recorders made before the use of electret elements are often good sounding
replacements in Kenwood mikes.

Please note that we have a Yahoo forum connected with this one called KenwoodMics. We probably should be discussing a lot of these mike issues there.

Art, the total cathode resistance should measure 5 ohms for proper operation of the finals and for metering accuracy. Something has probably gone wrong with the 4-20 ohm resistors. By unsoldering one end of each resistor you can check their values. I just had to replace mine in my TS-830 because their values had increased. Good luck.

Subject: [TS-520_820_530_830] ts-830s

We have a TS-830S and the output would fall off to around 80 watts
on 20 meters from around 105 watts so we order some new GE/JAN
6146W's and a new 12by7a driver. I installed the tubes today and
turn the rig on and let warm up some and then turned the heater
switch on and was going to let the tubes warm up for maybe 20
minutes before I would try and load the rig up on 20 meters. Band
switch was set for 20 meters and the mode switch was in usb. Well
maybe into warming up for around one minute the rig acted like
something shorted out twice and we turn it off. WE replaced the new
6146W tubes with the old 6146W tubes and now when we checked the
idle current it goes full scale. I pulled the final unit and
checked r2-r5 which are 20ohm resistors. They all check installed in
the board at 42.9ohms. Could someone please direct me into the
correct area to check and help me get this rig back on the air.
Thanks

Hi Bill, Thanks for the reply. You are correct about the 4-20 ohm resistors because that was what was wrong. I replaced all for and the total ohm is now 5.3 ohms. I put in some old 6146B tubes to try it out and things seemed to be ok but these tubes power falls off from 110 watts to around 85 watts. I was kinda afraid to put the new 6146W tubes back in the rig because that was maybe what caused the resisters to fail. These 6146W tubes are new and dated 1987 and we purchased them from Surplus Sales of Nebraska and received them today so I though I would replace the old 6146B tubes with these new 6146W tubes for the week end ARRL RTTY contest. These W tubes are GE/JAN BRAND and I am not sure if I should use them or try and find some B tubes which seem to cost much more than the W tube. Maybe you could help decide what to do because at this point I am not sure. Bill please give me your suggestions and what causes these resistors to fail?

Walt
That was very interesting and informative until I got to the part that (ESSB) started on 7.240 in the 1970's!!! That form of receiving has been used for years dating back much earlier than any hams getting together on 7.240 in the 70's.

Walt, from a newcomer to ham radio (licensed just one year) I want to thank you for your trip down "memory lane." Your reminiscenses were very educational to one who has been hearing names like Heil, but not really knowing any of the back story. Very interesting!

Subject: Re: [TS-520_820_530_830] as for MC-50 and MC-60

That is an olde trick. Actually, the MC-50 mike elements were lacking in
articulation. Covering the side holes with scotch tape, electrical tape, rubber, or a toilet paper
tube puts back pressure on the element making it more middy and adding articulation.

The best way I found was to remove the top cover. On the sides of the element there is nylon cloth or sometimes felt. Putting one layer of masking tape over this material will increase back pressure. Use two pieces,
one on each side between the wire connections. I found that if one on one
side is about 1/4 inch short to not fully cover that side it is a bit better. Masking tape lets just the right amount of air still pass. Be careful.

The MC-60 has many other issues. Most of these mikes had the hot audio and
the ground reversed inside the mike itself resulting in RF and response
problems. These are detailed in the files section of KenwoodMics Yahoo
group.

Now some history if I may reminiscence:

Many people think that if they purchase the factory matching mike they will
get great sound. Actually during the 70's and somewhat today, this was not
the case.
The manufactures would purchase generic elements and tailor a mike to
cosmetically match
their gear. The mike was not necessary optimum electrically.
Another problem was that these mikes were designed by people who spoke
Japanese.

In those days, lines of communications between the Japanese manufactures and
American users was poor. The Japanese language uses many vowels, the
a,e,i,o,u sounds. The American language uses more consonants, the c,k,s,t,
sounds. Mikes tailored for Japanese users did not work well
for English speaking Americans. They muffled the English language.

The MC-50 uses a sound reinforcement element that is good for Paging
applications and for the South East Asian languages. It is the same element
that is some models of the muddy Diesel CB noise canceling mike with the
screen front sold at truck stops.

In the mid 70's a group of us used to operate on 7240 late nights and
started wondering why some
rigs and mikes sounded clearer and had more punch than others. Among the
many was Bob Heil, K9EID. Bob, like myself always liked the TS-820. Bob
built custom audio mixers for performers. We started using various circuits
to enhance our audio including series capacitors, compressors, and
mechanical modifications such as the one above. We then started trying
different mike elements in our MC-50s. Heil located a source of a square
ceramic element that sounded much better than the MC-50 element. He called
it the Heil HC-1, Heil ceramic 1.

Over the next couple of years, Heil did a lot of research and had the
manufacture of these elements to custom make elements to his audio response
specifications. So along came the HC-2 and the HC-3.

Finally he settled on the HC-4 and HC-5. The HC-4 was a element meant to be
punchy with extreme mids but not natural sounding. It was for busting DX
pile ups. The HC-5 was a more full dynamic element in the same package but
had a subtle rise in the presence area to increase articulation. The HC-5
worked good in the MC-50.

Bob then built the EQ-100 which was based on the various active EQ projects
that we were doing on 7240. He published this as a project in QST. This was
followed by the EQ-200.

At Dayton engineers from Icom, Yaesu, and Kenwood attended his audio forums
and the result was greatly improved sound of the Asian made rigs. Imagine
how cool it was to have engineers from the major Amateur Radio manufactures
come to your forum to learn how to make their gear better!

Bob started making mikes using the HC elements and perfected the enclosure
design to enhance his elements. The enclosure has a lot to do with the
sound.

Heil later contracted the manufacture of some dynamic elements that were
physically more typical of normal dynamic elements but still had boosted
articulation. Heil started marketing headsets that the broadcast sports
industry picked up on. They typically used the HC-5 element.

Dynamic elements had not changed much for over 20 years, until the last
couple of years.
Then Heil, with the help of Joe Walsh, and a guy that has an outstanding
tool shop along with others came up with a new Dynamic design that used low
mass (light weight) wire and a quilted element, among other features found
in the $1000 mikes such as a hum bucking coil. Heil incorporated these new
elements in his Pro 20, 30, and 40 as well as in his Classic microphone
series.

The Pro 40 is really getting noticed by the broadcast industry. One of
those now replaces the 77 DX on David Letterman's desk. It has many of the
qualities of a condenser mike but does not require phantom power and does
not pop and hiss as bad as condensers do.

As Bob says, "It all starts with the microphone." All of this started with
efforts to improve the MC-50 microphone using tape and toilet paper
tubes!

Now some notes:

BTW, ESSB (enhanced single side band) is not new. It started on 7240 in the
mid 70's.

K0ZL pointed out that elements from microphones used with tape and cassette
recorders made before the use of electret elements are often good sounding
replacements in Kenwood mikes.

Please note that we have a Yahoo forum connected with this one called
KenwoodMics. We probably should be discussing a lot of these mike issues
there.

Want a Pro 40? The Fox Tango yahoo group is raffling off a Heil Pro-40 and a
H.F. mobile rig.

From: Walt Breining
Topic: 6299 Message: 6299

Probably, one or more of your new tubes has a screen to control grid short. This
placed high screen voltage on the control grid that should be biased near cut off with negative voltage. When the filaments warmed, the tube started conducting violently causing excessive current through the cathode resistors R2, R3, R4, and R5.

These resistors serve as shunt resistors for the IP meter and also act as fuses
in the event of a short like the one that happened to you.

You should replace R2, R3, R4, and R5.
Do not use resistors except 1/2 watt, the same wattage as the originals. Do NOT use larger resistors because they will not blow if needed and do major damage if this were to happen again.

Also check R7, R8, and L2. R7 and R8 are 100 ohms 1/2 watt. L2 coil should check 0 ohms. If it checks open, it is fried. Also look closely for cracks or any indication that it is badly fried. If it looks like it has gotten hot, not just dirt on it, it could be shorted.

Also check R1 100 ohms 1/2 watt and L1 choke coil. This chokes is checked the same way as L2. Observe PS 1 and PS 2. These are two parasitic chokes wound around a resistor. It is not likely that these were damaged and the wire or the resistor inside will look like it has been overheated if they are damaged. They may be covered. If so and the cover does not look burnt, don't
worry about them for now.

After doing the above put your ORIGINAL tubes in and try again. After the filaments warm up, key up in SSB with mike gain fully down and see if you can set your bias control for 60 ma IP.

Let us know what happens. Even if the rig is now back to it's original condition, get back with us.

I am interested as to why you concluded that the tubes were bad and what type and make the originals were. 6146 and S-2001 types do not go bad as often as the 6JS6 tubes in Yaesus do unless the rig has been hot rodded. I am not as familiar with the TS 830 as I am the 820, but screen supply problems can cause low output. I can help you check that.

Remember that the SG switch on the back has to be on. It often gets bumped while servicing.

To check the new tubes for shorts, check ohms between pin 3 and 5 with the tube removed. If it shows anything but an open, it is shorted. If it shows

a very high resistance, like 100k ohms or more, check to be sure that your fingers are not touching the probes. Likely you will be measuring yourself.

With the bottom of the tube facing you, you will see a pin with a key along the side. This lines up with the key hole in the socket to establish tube rotation.

Still with the bottom facing you count clockwise from the key. The first pin clockwise from the key is pin 1 the last pin clockwise is pin 8.

Pin 3 is the screen grid and pin 5 is the control grid. These are the pins where the short will be.

If the tubes show a short, they are shorted. If they show a open, they may still be shorted and should be checked in a Tube Tester for shorts before trying them again. Do not be too quick to have a public hanging of the person who sold you these tubes. These grids can often short during shipment and handling. Some makes and types tend to do this more than others.

BTW, does everybody understand how a tube works basically?

Please tell me what you mean by "that form of receiving"? I will comment.

You are right. Good sounding transmit audio was not new in the 70's. It was always a goal since the beginning of AM. However until the mid 70's most SSB signals sounded pretty bad. There very likely some other pioneers prior to that seriously trying to improve their SSB sound. Not just make it louder.

Where Heil is today regarding his microphone and Amateur endeavors did start in the mid 70's. One point I wanted to make is that Good audio is nothing new. And "Good audio is an Amateur Radio tradition, not a crime."

Guys, look into a swing-arm stand such as that sold by
Heil, and also perhaps modifying one from a desk lamp.
That and a foot switch is the best thing I have ever
done for my station; REALLY came in handy during
Katrina comms.

Does anyone have a source for 20 ohm resistors? I
can't seem to find them in any of the usual places. I
finally replaced my 4 20 ohm 1/2 watt units with 2 10
ohm 1 watt units until I can find the real thing.

Thanks,

Mike, WC0L

Topic: 6304 Message: 6304

Hello All,

The plastic inside the chassis din connector has cracked on my TS-830 for the transverter connector. There is also a switch housing that is attached to the din chassis. I see that on Kenwoodparts.com that the part for it has been discontinued. It appears that if I remove the two screws and seperate the socket from the chassis of the radio, and then unsolder all of the wires, the center plastic piece should come out thre front of the connector. I am thinking of getting a standard 8 pin chassis din and using the center plastic piece and inserting it into the old din housing. Has anyone tried this or have a better way of replacing this din connector.

Thanks,

Mark, K9MQ

Good Morning Art. I had just done the exact same thing (replaced 6146B's with 6146W's JAN type) a few hours before my cathode resistors blew. However, since I had performed all the neutralizing procedures and loaded up the radio several times with no problem, I think I had a "senior moment" type of thing that caused the resistors to blow. Users much more experienced with these radios than I, tell me there is no problem associated with using 6146W tubes. When I was in there changing out the cathode resistors, I also installed new screen resistors because one of them had changed value, but I don't think this was any part of my problem. Most resistors increase in value with age, so I imagine any you checked in these older radios would show more resistance than when they were new.

One thing I learned in the neutralizing process is that using a 2nd receiver to sense the output can lead to confusing results. I finally switched to my RF Probe and measured the output voltage across the dummy load, and this procedure seemed to give very consistent indications that were not affected by the movements of my body, etc. In my opinion, neutralization should be checked anytime something is moved or replaced on the Final Amp Board. I was told that improper neutralization could cause an oscillation that would produce excessive current that would blow the cathode resistors. These resistors in parallel are rated at 5 ohms at 2 watts power dissipation in order to provide protection for the tubes and power supply just in case someone like me has a "senior moment". I now watch Ip instead of ALC when transmitting so I at least have a chance of detecting if something goes wrong - but these things do happen very fast. Just make sure you know what type of Ip meter swing gives you proper ALC readings.

I was also told to set the idling current in the area of 45ma to 50ma instead of the 60ma specified to increase tube life without really affecting operation. The other caution I got was to limit final current when tuning up to about 225ma instead of the 265ma specified in my manual.

That's about all I know at this point because I just got my TS-830 about 3 weeks ago, and my experience is very limited so far. So maybe someone else with more experience will step in and provide more information as to what other things could cause the cathode resistors to burn up. I do plan to begin some of the alignment procedures after I operate the radio a while. The "go no-go" decision of "B" vs. "W" will have to be yours since I have been told that either one is fine.

Good luck in the contest, and don't let the RTTY duty cycle damage your radio Art.

73, Bill, K5GCW

Hi Bill, Thanks for the reply. You are correct about the 4-20 ohm resistors because that was what was wrong. I replaced all for and the total ohm is now 5.3 ohms. I put in some old

6146B tubes to try it out and things seemed to be ok but these tubes power falls off from 110 watts to around 85 watts. I was kinda afraid to put the new 6146W tubes back in the rig because that was maybe what caused the resisters to fail. These 6146W tubes are new and dated 1987 and we purchased them from Surplus Sales of Nebraska and received them today so I though I would replace the old 6146B tubes with these new 6146W tubes for the week end ARRL RTTY contest. These W tubes are GE/JAN BRAND and I am not sure if I should use them or try and find some B tubes which seem to cost much more than the W tube. Maybe you could help decide what to do because at this point I am not sure. Bill please give me your suggestions and what causes these resistors to fail?

Art, the total cathode resistance should measure 5 ohms for proper operation of the finals and for metering accuracy. Something has probably gone wrong with the 4-20 ohm resistors. By unsoldering one end of each resistor you can check their values. I just had to replace mine in my TS-830 because their values had increased. Good luck.

We have a TS-830S and the output would fall off to around 80 watts
on 20 meters from around 105 watts so we order some new GE/JAN
6146W's and a new 12by7a driver. I installed the tubes today and
turn the rig on and let warm up some and then turned the heater
switch on and was going to let the tubes warm up for maybe 20
minutes before I would try and load the rig up on 20 meters. Band
switch was set for 20 meters and the mode switch was in usb. Well
maybe into warming up for around one minute the rig acted like
something shorted out twice and we turn it off. WE replaced the new
6146W tubes with the old 6146W tubes and now when we checked the
idle current it goes full scale. I pulled the final unit and
checked r2-r5 which are 20ohm resistors. They all check installed in
the board at 42.9ohms. Could someone please direct me into the
correct area to check and help me get this rig back on the air.
Thanks

Hi Mike.

From all I could find out, using 2 - 10 ohm, 1 watt resistors is the common solution, and that is what I did. The first set blew up real fast when I messed up, so they must work ok! I did not check the big parts distributors, so the 20 ohm 1/2 watt resistors may be out there. I have 20 ohm 1 watt resistors in my junk box, but sure glad I didn't use them!

Does anyone have a source for 20 ohm resistors? I
can't seem to find them in any of the usual places. I
finally replaced my 4 20 ohm 1/2 watt units with 2 10
ohm 1 watt units until I can find the real thing.

Thanks,

Mike, WC0L

Mark,

I assume that the connector in question is the 8-pin DIN external VFO connector. Be aware that there are two standards of 8-pin DIN connectors, although if you can change the inner then perhaps you can fit whichever type you have at hand.

I had to make up an external VFO cable for my TS-530 and found that most stockists of 8-pin DIN connectors didn't stock the version that I needed. Fortunately, I managed to track down a supplier, but not before damaging the chassis connector on the VFO through trying to insert the wrong type.

Hi Walt,
Thank you for helping me. OK we checked the new 6146W for a short between pins 3 and 5 and there is NO short on either tube. Now this check was done via an ohm meter because I do not have access to a tube checker. We checked R7-R8 and they checked 100.2 and 100.0 OHMS. PS 1 and ps 2 look to be OK. Now L2 on the board checks 4.2 OHMS NOT ZERO OHMS it does not look like it has been fried. L1 on the board checks 1.8 OHMS. We tried the old tubes and they seem to work OK. These are 6146B's which lose power during transmit. Set idle current to 60ma with no problem. With the B tubes things seem to be like they were.

Any other suggestions?

There were several great sounding phasing type SSB transmitters/exciters
in the 50's. With the introduction of "filters" into the SSB audio chain,
audio quality started to deteriorate.

Pete, wa2cwa

On Fri, 6 Jan 2006 07:47:11 -0500 "Walt Breining" <n9wb@...> writes:
Please tell me what you mean by "that form of receiving"? I will
comment.

You are right. Good sounding transmit audio was not new in the 70's. It
was
always a goal since the beginning of AM. However until the mid 70's most
SSB signals sounded pretty bad. There very likely some other pioneers
prior
to that seriously trying to improve their SSB sound. Not just make it
louder.

Where Heil is today regarding his microphone and Amateur endeavors did
start
in the mid 70's. One point I wanted to make is that Good audio is
nothing
new. And "Good audio is an Amateur Radio tradition, not a crime."

Bill, Thanks for the info on L2. The meter I use is kinda cheap so not sure how accurate but probably pretty close from what reading I get to what it should be. Did you say you were also using GE/Jan 6146W tubes? There has to be some problem I am missing so right now we are waiting on Walt to see what the next step will be. I was looking at the 6146W tubes at RF PARTS and saw a recommendation that the 6146W GE tube was not recommended for the Kenwood transceivers. So this might be why I am have the problem.

6314. Re: [TS-520_820_530_830] R2-R5 Failure

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-06 21:38:10 UTC
From: Bill Scurlock
Topic: 6308 Message: 6314

Art, the new 6146W tubes I used came as spares with the radio when I bought it. I do not remember for sure who manufactured them, and I can't find their boxes. I do remember that they had the JAN marking on them. I will try again to find their boxes. Thanks for the warning from RF Parts. I went to their website and found what you said, but they didn't give the reason why. My power output is still low, 50 - 80 watts, depending on the band - so my problem is not solved yet. Maybe I should just try 6146B's and see if that is the reason for my low power output problem. More later.

Bill, Thanks for the info on L2. The meter I use is kinda cheap so not sure how accurate but probably pretty close from what reading I get to what it should be. Did you say you were also using GE/Jan 6146W tubes? There has to be some problem I am missing so right now we are waiting on Walt to see what the next step will be. I was looking at the 6146W tubes at RF PARTS and saw a recommendation that the 6146W GE tube was not recommended for the Kenwood transceivers. So this might be why I am have the problem.

Hi Walt,
Thank you for helping me. OK we checked the new 6146W for a short
between pins 3 and 5 and there is NO short on either tube. Now this
check was done via an ohm meter because I do not have access to a tube
checker. We checked R7-R8 and they checked 100.2 and 100.0 OHMS. PS 1

and ps 2 look to be OK. Now L2 on the board checks 4.2 OHMS NOT ZERO OHMS it does not look like it has been fried. L1 on the board checks 1.8 OHMS. We tried the old tubes and they seem to work OK. These are 6146B's which lose power during transmit. Set idle current to 60ma with no problem. With the B tubes things seem to be like they were.

Any other suggestions?

Bill, It seems to me we are have the same problem. Before I went to pick up the grandson I tried GE 6146B's and was able to get about 75 watts out then we put in the sav 6146W's and the output was at 60 watts it is almost like the output of one tube instead of two. These checks were on 28.800 10 meters and after I neutralized them. What do you think?

Well, it could be Art. I did find the tube boxes, but all they said was JAN 6146W with no reference to the manufacturer. So guess I will have to open up the radio again and pull the tubes to find out who made them. I have a couple of RCA 6146B's that were pull-outs from something years ago, one new Sylvania 6146B, and 3 matched RCA 6146B spares for my FT-102 (which I don't want to breakup by using any). So....., guess my next step will be to check my old tubes with my Heath Tube Checker and see if I find any shorts or other obvious problems. Wish I had a "real" tube checker.

It is hard for me to compare what good I have done by installing the new tubes because the cathode resistors had changed value (about 7.5 ohms) when the original tubes were installed. When I changed the tubes out was when I found the cathode resistor problem, and changed them to obtain 5 ohms. At least now Ip reads somewhere closer to actual current. As I recall, the tube change and resistor fix only gained about 15-20 watts output. I just had a QSO on 20M this afternoon and all the output I could get was about 55W. It is about 75W on 80M. The indicated HV at idling current is about 910V, and, at tuneup current, it is about 810V. Assuming reasonable meter accuracy, this gives about 160W+ input. Is this similar to what you are getting?

We will be very proficient at neutralizing before this is over! I probably won't have time to mess with all this anymore today Art. Let me know how you come out, and I will do the same. Maybe some expert will step forward and give us an obvious answer to something we are overlooking.

Have a good evening Art. I don't get to see my grandchildren until sunday.

Bill, OK on the grandson ours is spending the night with grandma and grandpa till tomorrow morning. The high voltage I get from this rig is 890 volts unkeyed and 780 volts keyed. I think the cause is low voltage at the wall plug. I have been trying to find a voltage chart on the tubes pins so we could check that area but I though was in the Manuel but do not find it. If you know what the voltages should be on the pins of the 6146 please let me know. Have a great week end.

Subject: [TS-520_820_530_830] R2-R5 Failure

Hi Walt,
Thank you for helping me. OK we checked the new 6146W for a short between pins 3 and 5 and there is NO short on either tube. Now this check was done via an ohm meter because I do not have access to a tube checker. We checked R7-R8 and they checked 100.2 and 100.0 OHMS. PS 1 and ps 2 look to be OK. Now L2 on the board checks 4.2 OHMS NOT ZERO OHMS it does not look like it has been fried. L1 on the board checks 1.8 OHMS. We tried the old tubes and they seem to work OK. These are 6146B's which lose power during transmit. Set idle current to 60ma with no problem. With the B tubes things seem to be like they were.

Any other suggestions?

Art:

Sorry, I've been away from the computer. If you have the rig back as before, I was thinking about screen voltage problems. Th have less output on 10 meters is normal but you are low everywhere.

I usually normally see over 100 watts on all bands to 15 meters. It is usually a bit down on 15 and at least 80 to 90 watts on 10 meters. That is fully peaked for max out into a flat load using a accurate meter. These are conservative readings as often normal is a bit higher.

Now that I know that the output seems to fade, I would think of weak tubes as you have, how since you don't have safe spares to try, It doesn't cost money to check the #2 most likely cause.

I am more familiar with the 820 than the 830 so I am going to look at my very poor copy of the 830 diagram and get back to you on the screen voltage problem.

Are you using the new 12BY7 ?

Probably your choke readings are normal. I should have said, Near Zero.

> Bill, Thanks for the info on L2. The meter I use is kinda cheap so not sure how accurate but probably pretty close from what reading I get to what it should be. Did you say you were also using GE/Jan 6146W tubes? There has to be some problem I am missing so right now we are waiting on Walt to see what the next step will be. I was looking at the 6146W tubes at RF PARTS and saw a recommendation that the 6146W GE tube was not recommended for the Kenwood transceivers. So this might be why I am have the problem.

6320. Testing Finals

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-07 14:30:40 UTC
From: Walter A. Breining
Topic: 6320 Message: 6320

The following procedure is for checking for weak tubes. I do suggest a tube tester to check for shorts.

Caution: If you suspect that a tube is shorted, do NOT put it in your rig. Walt N9WB

I have also placed the following in the files section of this group for easier future access.

Testing Tubes, a previous post by Bill, K0ZL.

Tube testers cannot be trusted for transmitting tubes.

Here's how I do it.

Hook up to a dummy load, first. This is always the first step in testing a rig as it eliminates the antenna and feedline as a source of trouble, and keeps you legal.

Now locate the SG switch on the back panel and make sure it is ON. If it's OFF, that is the source of your trouble. The SG switch, when OFF, will bias your finals OFF for use with a transverter, or to prevent accidental transmissions (say, when kids are around).

Make sure your FILament switch is on (applies to all except early TS-520 and the TS-530 I think). Tubes should warm up for three minutes.

CHECKING THE FINAL TUBES
Put the rig in SSB mode and transmit. For the TS-820, 530 and 830 only, use the front panel meter to check the HV; should be above 800 volts (meter scale is 0-1000 volts, so needle should be way past mid-scale). Note, that the HV reading only works in TX mode. For all other tube rigs, you will need to use a bench meter to check plate voltage; put that off for now.

Next, locate the plate idle bias current control; on the 520/820 it's in the back of the rig, under the fan; on the 830, it's on the side. On the 530, I forget where it is (someone fill me in).

Go back into TX mode, SSB, and observe the plate idle current. Now, go to Ip and read the plate current. It should be your normal idle current, of 50-60 mA. If not, adjust the bias control until it is. If you

cannot reach 50-60mA, double-check the SG switch. If the SG switch is ON, you have other problems. Stop here.

If you were able to effect normal bias current, then turn the plate bias control ALL THE WAY CLOCKWISE (UP)! QUICKLY observe the new plate current reading, and whether it hangs there, or drops off rather quickly. JUST AS QUICKLY reduce the plate idle bias current back down to 50-60mA and go back to RX mode.

Idle bias should have reached above 200mA. If not, one or both final tubes could be bad, or there are other problems. If the idle bias current came up nice and high, and then dropped off RAPIDLY, you have one or more bad final tubes. Replace them. If the idle current came up and stayed up, or started to decrease very slowly, the finals are good.

Make sure you have attained normal idle bias current of 50-60mA before proceding.

CHECKING THE DRIVER TUBE
Switch the meter to ALC, put the rig in TUNE mode, and then transmit. Peak the ALC reading with the DRIVE tuning control. Adjust with the CAR control as needed to keep the meter between 1/2 and full scale. Go back into RX mode and let the driver tube cool for a few seconds. Now without touching the other controls, go into TX mode again, and observe the action of the ALC meter:

-If it comes up and stays up, the driver tube is fine.

- If it comes up and then drops off rapidly, you have a bad driver tube.

- If you cannot get any ALC reading at all, make sure your filament switch did not get bumped to the OFF position. If you still cannot get any ALC reading, you may have a bad driver or, more likely, something else is wrong; either you are on a WARC band (30, 17 or 12 meters) and the rig has not been enabled for WARC yet, or the RF deck needs alignment or there is a fault somewhere.

By now you should have a pretty good idea of whether your tubes are bad or not. Roughly 80 percent of the rigs that come through my shop for "finals" actually have other things wrong with them and the tubes are fine. 15 percent need a new driver tube, and 5 percent need finals.

Tubes are not cheap, and they are not all that plentiful. Let's try to check them before changing them and help to preserve our supply!

NOTE TO GROUP MEMBERS: THIS text will be part of a "tube condition FAQ" and I need corrections to be sent to me before I "PDF" it. Please keep the new subject line intact so I can pick up all related posts to include in the PDF.

73,

Bill K0ZL

Al:
Either I am getting older or the lines on my poor diagram copy are getting closer. In any event:

After further investigation, the possible screen divider failure I mentioned earlier would only affect the tune mode so It is not the cause of your problem.

However I did find something that might be worth checking.

R-11 a 470 ohm resistor on the Rectifier Unit board. If it were high, it could cause low output.

Caution!
There are capacitors on this board that store high voltage. Follow the following procedure.

Before attempting to work on this take the following precautions.

Unplug the transceiver from AC mains and let it sit for about 5 minutes. Using a clip lead or a screwdriver, short the following terminals on the Rectifier unit board to chassis ground. HV, 800, 300, 210A, 210B, C-. The capacitors hold charges. Failure to follow the above procedure can result in injury or death.

It is looking more like the original tubes are weak and one of the new ones is shorted. I have posted a procedure by K0ZL for testing the olde ones. I'd be hesitant to try the new ones again.

6322. Re: [TS-520_820_530_830] ts-830s

Hi Art,
Most likely the new final tubes are shorted, poss. due
to shipping damage.

The cathode resistors are blown, as they should read a
total of 5 ohms to ground if all four are good.

Topic: 6308 Message: 6323

Good Morning Walt. I just installed new JAN 6146W's and a new 12BY7A and am generally experiencing the same low power output problem with my TS-830 as Art - and I have been following your comments.

Where is the best location to measure the screen voltage, and what is an acceptable range of values to expect? I assume this should be done under transmit load conditions. I am familiar with the safety issues in making these types of measurements.

At idle current of about 50ma, my HV is just a little over 900V, and at about 215ma the HV is a little over 800V. I've already changed out the cathode resistors to obtain the 5 ohm total resistance, and I changed out the two screen resistors on the final tube board so they have exactly the same resistance. My power output on 20M is about 55 watts, and on 80M it is about 75 watts.

Your comments would be appreciated. Thanks.

Bill, K5GCW

Hi Walt, Thanks for the information on R11. We will check it out and see if that could be a problem. On the new 6146W tubes I guess we will call the company I got them from and see if they will replace them.

I'm wondering if you are measuring CW output or peak SSB output. If you are measuring SSB on an averaging meter your output will be about 1/2 CW. I've been using 6146W tubes in my TS-530 and FT-901DM (Philips in one and GE in the other) for a number of years and get 100W+ output on CW.

6326. Shure 444 info

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-07 21:09:17 UTC
From: Walter A. Breining
Topic: 6326 Message: 6326

For those who are seeking Shure 444 information. I finally have the datasheet for the Shure 444 D on KenwoodMics at the following link. This the dual impedance version.

http://groups.yahoo.com/group/KenwoodMics/files/Shure%20444/

I have the data sheet for the 444 high impedance only version but it is in PDF and I am unable to figure out to convert it to a format that Yahoo Groups will accept. If you need it e-mail me and I will send the PDF file to you.

Hi Stephen, Have you tried the GE/JAN 6146W in your TS-530? The problem I had with these tubes is after putting them in the rig I turned the TS-830S on and then turned the Heater switch on and in around a minute then took out R2-R5 on the Final unit board. I assume the tubes are shorted to cause this. Have you ever had this problem ?

I'm wondering if you are measuring CW output or peak SSB output. If you are measuring SSB on an averaging meter your output will be about 1/2 CW. I've been using 6146W tubes in my TS-530 and FT-901DM (Philips in one and GE in the other) for a number of years and get 100W+ output on CW.

Art,
Yes the 530 has been running with GE 6146W finals for almost 7 years with no problem. Tried a pair of Chinese 6146Bs first and they shorted as soon as I tried to tune up. Replaced them with the GEs from RF Parts. They had no warnings about them at that time. I burned them in for 24 hours with filaments on but no transmission and they've been going strong ever since.

6330. Re: [TS-520_820_530_830] R2-R5 Failure

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-08 00:33:48 UTC
From: Bill Scurlock
Topic: 6308 Message: 6330

Art, I spent the afternoon making a bunch of measurements, and have about concluded that my low power output is not tube related. I changed out the 6146W's for some old Sylvania 6146B's and got the same power output on 20M (55W) and on 80M (75W). I spent several hours measuring the 6146 HV, Screen voltage, and Grid bias under both receive and transmit conditions. Also the 210A and 300B voltages on the power board. All looked at least as high as shown on the schematic drawing, and very close to the values indicated. So I'm back to square one for now.

We're going to a movie. Probably be back on this next week. 73,

Bill, K5GCW

Al:
Either I am getting older or the lines on my poor diagram copy are getting closer. In any event:

After further investigation, the possible screen divider failure I mentioned earlier would only affect the tune mode so It is not the cause of your problem.

However I did find something that might be worth checking.

R-11 a 470 ohm resistor on the Rectifier Unit board. If it were high, it could cause low output.

Caution!
There are capacitors on this board that store high voltage. Follow the following procedure.

Before attempting to work on this take the following precautions.

Unplug the transceiver from AC mains and let it sit for about 5 minutes. Using a clip lead or a screwdriver, short the following terminals on the Rectifier unit board to chassis ground. HV, 800, 300, 210A, 210B, C-. The capacitors hold charges. Failure to follow the above procedure can result in injury or death.

It is looking more like the original tubes are weak and one of the new ones is shorted. I have posted a procedure by K0ZL for testing the olde ones. I'd be hesitant to try the new ones again.

How are you measuring the output power ? On a 50 watt dummy load ?

6333. RE: [TS-520_820_530_830] ts-830S

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-08 01:46:46 UTC
From: Hauser, Ron M.
Topic: 6299 Message: 6333

Hi Art. I got a TS-830S recently and found that it had pretty soft
power. After good advice from this group, I checked r2-r5 and found
that they were all out of spec. Nothing was out and out fried, but they
were way out of tolerance. When pulling them out of the board, most of
them crumbled. I interpret this to be long term degradation due to heat
off of the tubes.

Anyway, in my case after replacing the resistors, I was back at a good
solid 100W with the same old same old tubes. I bring this up in the
context of Walt's question about how you decided your tubes were soft to
begin with... Might your "old" tubes have been solid and your r2-r5 have
been degraded? Perhaps also if your r2-r5 were degraded, then the hot
might have just pushed them over the edge. It will be very interesting
to see the results of your tests, please post them.

Subject: Re: [TS-520_820_530_830] ts-830S

Probably, one or more of your new tubes has a screen to control grid
short.
This
placed high screen voltage on the control grid that should be biased
near
cut off with negative voltage. When the filaments warmed, the tube
started
conducting violently causing excessive current through the cathode
resistors
R2, R3, R4, and R5.

These resistors serve as shunt resistors for the IP meter and also act
as
fuses
in the event of a short like the one that happened to you.

You should replace R2, R3, R4, and R5.
Do not use resistors except 1/2 watt, the same wattage as the originals.
Do
NOT use larger resistors because they will not blow if needed and do

major
damage if this were to happen again.

Also check R7, R8, and L2. R7 and R8 are 100 ohms 1/2 watt. L2 coil should
check 0 ohms. If it checks open, it is fried. Also look closely for cracks
or any indication that it is badly fried. If it looks like it has gotten
hot, not just dirt on it, it could be shorted.

Also check R1 100 ohms 1/2 watt and L1 choke coil. This chokes is checked
the same way as L2. Observe PS 1 and PS 2. These are two parasitic chokes
wound around a resistor. It is not likely that these were damaged and the
wire or the resistor inside will look like it has been overheated if they
are damaged. They may be covered. If so and the cover does not look burnt,
don't
worry about them for now.

After doing the above put your ORIGINAL tubes in and try again. After the
filaments warm up, key up in SSB with mike gain fully down and see if you
can set your bias control for 60 ma IP.

Let us know what happens. Even if the rig is now back to it's original
condition, get back with us.

I am interested as to why you concluded that the tubes were bad and what
type and make the originals were. 6146 and S-2001 types do not go bad as
often as the 6JS6 tubes in Yaesus do unless the rig has been hot rodded. I
am not as familiar with the TS 830 as I am the 820, but screen supply
problems can cause low output. I can help you check that.

Remember that the SG switch on the back has to be on. It often gets bumped
while servicing.

To check the new tubes for shorts, check ohms between pin 3 and 5 with the
tube removed. If it shows anything but an open, it is shorted. If it shows
a very high resistance, like 100k ohms or more, check to be sure that your
fingers are not touching the probes. Likely you will be measuring
yourself.

With the bottom of the tube facing you, you will see a pin with a key
along
the side. This lines up with the key hole in the socket to establish
tube
rotation.

Still with the bottom facing you count clockwise from the key. The first
pin
clockwise from the key is pin 1 the last pin clockwise is pin 8.

Pin 3 is the screen grid and pin 5 is the control grid. These are the
pins
where the short will be.

If the tubes show a short, they are shorted. If they show a open, they
may
still be shorted and should be checked in a Tube Tester for shorts
before
trying them again. Do not be too quick to have a public hanging of the
person who sold you these tubes. These grids can often short during
shipment and handling. Some makes and types tend to do this more than
others.

BTW, does everybody understand how a tube works basically?

Hi Mike. I had to do the R2-R5 replace, and when I counted up the price for four of them, plus four spares, it was basically cheaper to buy a hundred. I bought them from Mouser for something like six bucks. www.mouser.com

Does anyone have a source for 20 ohm resistors? I
can't seem to find them in any of the usual places. I
finally replaced my 4 20 ohm 1/2 watt units with 2 10
ohm 1 watt units until I can find the real thing.

Thanks,

Mike, WC0L

Allelectronics carries these resistors, 10 for .50 USD. They give good
service. They are on the web at: allelectronics.com

Subject: Re: [TS-520_820_530_830] R2-R5 Failure

Well, it could be Art. I did find the tube boxes, but all they said was JAN 6146W with no reference to the manufacturer. So guess I will have to open up the radio again and pull the tubes to find out who made them. I have a couple of RCA 6146B's that were pull-outs from something years ago, one new Sylvania 6146B, and 3 matched RCA 6146B spares for my FT-102 (which I don't want to breakup by using any). So....., guess my next step will be to check my old tubes with my Heath Tube Checker and see if I find any shorts or other obvious problems. Wish I had a "real" tube checker.

It is hard for me to compare what good I have done by installing the new tubes because the cathode resistors had changed value (about 7.5 ohms) when the original tubes were installed. When I changed the tubes out was when I found the cathode resistor problem, and changed them to obtain 5 ohms. At least now Ip reads somewhere closer to actual current. As I recall, the tube change and resistor fix only gained about 15-20 watts output. I just had a QSO on 20M this afternoon and all the output I could get was about 55W. It is about 75W on 80M. The indicated HV at idling current is about 910V, and, at tuneup current, it is about 810V. Assuming reasonable meter accuracy, this gives about 160W+ input. Is this similar to what you are getting?

We will be very proficient at neutralizing before this is over! I probably won't have time to mess with all this anymore today Art. Let me know how you come out, and I will do the same. Maybe some expert will step forward and give us an obvious answer to something we are overlooking.

Have a good evening Art. I don't get to see my grandchildren until sunday.

Bill, It seems to me we are have the same problem. Before I went to pick up the grandson I tried GE 6146B's and was able to get about 75 watts out then we put in the sav 6146W's and the output was at 60 watts it is almost like the output of one tube instead of two. These checks were on 28.800 10 meters and after I neutralized them. What do you think?

Art, the new 6146W tubes I used came as spares with the radio when I bought it. I do not remember for sure who manufactured them, and I can't find their boxes. I do remember that they had the JAN marking on them. I will try again to find their boxes. Thanks for the warning from RF Parts. I went to their website and found what you said, but they didn't give the reason why. My power output is still low, 50 - 80 watts, depending on the band - so my problem is not solved yet. Maybe I should just try 6146B's and see if that is the reason for my low power output problem. More later.

Bill, Thanks for the info on L2. The meter I use is kinda cheap so not sure how accurate but probably pretty close from what reading I get to what it should be. Did you say you were also using GE/Jan 6146W tubes? There has to be some problem I am missing so right now we are waiting on Walt to see what the next step will be. I was looking at the 6146W tubes at RF PARTS and saw a recommendation that the 6146W GE tube was not recommended for the Kenwood transceivers. So this might be why I am have the problem.

Art, the L2 resistance reading on my TS-830 is 3.8 ohms, so your 4.2 ohms is probably ok (or else I also have a problem!)

Subject: [TS-520_820_530_830] R2-R5 Failure

Hi Walt,
Thank you for helping me. OK we checked the new 6146W for a short
between pins 3 and 5 and there is NO short on either tube. Now this
check was done via an ohm meter because I do not have access to a tube
checker. We checked R7-R8 and they checked 100.2 and 100.0 OHMS. PS 1
and ps 2 look to be OK. Now L2 on the board checks 4.2 OHMS NOT ZERO
OHMS it does not look like it has been fried. L1 on the board checks
1.8 OHMS. We tried the old tubes and they seem to work OK. These are
6146B's which lose power during transmit. Set idle current to 60ma
with no problem. With the B tubes things seem to be like they were.

Any other suggestions?

Hi Patrick.

Thanks for the un-intended humor - I needed that. It's a nice old 500 watt 50 ohm dummy load that works with my wattmeter to indicate accurate power output from my other radios such as Icom 751A and Collins KWS-1, so I'm not suspect of it right now. But knowing that "Murphy" is always around, I had already decided to rig up another metering arrangement next week just to make absolutely sure. I've also loaded up into a well matched antenna on 75M and I get virtually the same indicated output from the TS-830. Have a good weekend Patrick.

6338. Re: [TS-520_820_530_830] R2-R5 Failure

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-08 05:37:31 UTC
From: Bill Scurlock
Topic: 6308 Message: 6338

Art, in searching for the voltage info today, I looked at the schematic and that info is on there. If you have not downloaded the schematic yet, let me know and I will try to send it to you as an email attachment. Please respond to my email address k5gcw@... and be sure to give me your direct email address so we can do this off the reflector.

Bill, OK on the grandson ours is spending the night with grandma and grandpa till tomorrow morning. The high voltage I get from this rig is 890 volts unkeyed and 780 volts keyed. I think the cause is low voltage at the wall plug. I have been trying to find a voltage chart on the tubes pins so we could check that area but I though was in the Manuel but do not find it. If you know what the voltages should be on the pins of the 6146 please let me know. Have a great week end.

Well, it could be Art. I did find the tube boxes, but all they said was JAN 6146W with no reference to the manufacturer. So guess I will have to open up the radio again and pull the tubes to find out who made them. I have a couple of RCA 6146B's that were pull-outs from something years ago, one new Sylvania 6146B, and 3 matched RCA 6146B spares for my FT-102 (which I don't want to breakup by using any). So....., guess my next step will be to check my old tubes with my Heath Tube Checker and see if I find any shorts or other obvious problems. Wish I had a "real" tube checker.

It is hard for me to compare what good I have done by installing the new tubes because the cathode resistors had changed value (about 7.5 ohms) when the original tubes were installed. When I changed the tubes out was when I found the cathode resistor problem, and changed them to obtain 5 ohms. At least now Ip reads somewhere closer to actual current. As I recall, the tube change and resistor fix only gained about 15-20 watts output. I just had a QSO on 20M this afternoon and all the output I could get was about 55W. It is about 75W on 80M. The indicated HV at idling current is about 910V, and, at tuneup current, it is about 810V. Assuming reasonable meter accuracy, this gives about 160W+ input. Is this similar to what you are getting?

We will be very proficient at neutralizing before this is over! I probably won't have time to mess with all this anymore today Art. Let me know how you come out, and I will do the same. Maybe some expert will step forward and give us an obvious answer to something we are overlooking.

Have a good evening Art. I don't get to see my grandchildren until sunday.

Bill, It seems to me we are have the same problem. Before I went to pick up the grandson I tried GE 6146B's and was able to get about 75 watts out then we put in the sav 6146W's and the output was at 60 watts it is almost like the output of one tube instead of two. These checks were on 28.800 10 meters and after I neutralized them. What do you think?

Subject: Re: [TS-520_820_530_830] R2-R5 Failure

Art, the new 6146W tubes I used came as spares with the radio when I bought it. I do not remember for sure who manufactured them, and I can't find their boxes. I do remember that they had the JAN marking on them. I will try again to find their boxes. Thanks for the warning from RF Parts. I went to their website and found what you said, but they didn't give the reason why. My power output is still low, 50 - 80 watts, depending on the band - so my problem is not solved yet. Maybe I should just try 6146B's and see if that is the reason for my low power output problem. More later.

Bill, Thanks for the info on L2. The meter I use is kinda cheap so not sure how accurate but probably pretty close from what reading I get to what it should be. Did you say you were also using GE/Jan 6146W tubes? There has to be some problem I am missing so right now we are waiting on Walt to see what the next step will be. I was looking at the 6146W tubes at RF PARTS and saw a recommendation that the 6146W GE tube was not recommended for the Kenwood transceivers. So this might be why I am have the problem.

Art, the L2 resistance reading on my TS-830 is 3.8 ohms, so your 4.2 ohms is probably ok (or else I also have a problem!)

Subject: [TS-520_820_530_830] R2-R5 Failure

Hi Walt,
Thank you for helping me. OK we checked the new 6146W for a short between pins 3 and 5 and there is NO short on either tube. Now this check was done via an ohm meter because I do not have access to a tube checker. We checked R7-R8 and they checked 100.2 and 100.0 OHMS. PS 1 and ps 2 look to be OK. Now L2 on the board checks 4.2 OHMS NOT ZERO OHMS it does not look like it has been fried. L1 on the board checks 1.8 OHMS. We tried the old tubes and they seem to work OK. These are 6146B's which lose power during transmit. Set idle current to 60ma with no problem. With the B tubes things seem to be like they were.

Any other suggestions?

From: Arthur Petteway
Topic: 6299 Message: 6339

Hi Ron, Thanks for the information and interest. Well the reason I felt the 6146B tubes were bad is because I could key the rig and it would show over 100 watts and then the power would drop to around 85 watts and seem to stabilize there. I figured it was a final problem or the driver was bad. I put some old 6146W tubes which were different brands but they held the power out around 100 watts and did not lose power. So I figured I would order some new 6146W's because they seemed to work ok with just a little less power output. So we received the new GE/JAN 6146W tubes and a new 12BY7A driver and we installed them and that is when my problem started with the R2-R5 resistors. Those resistors failed when we turn on the heater switch. No load rig was in receive.So figure the new finals had a short but cannot find one with the ohm meter and that is how things stand at this point.Maybe next week we will be able to dig into the rig a little farther.

Subject: RE: [TS-520_820_530_830] ts-830S

Hi Art. I got a TS-830S recently and found that it had pretty soft
power. After good advice from this group, I checked r2-r5 and found
that they were all out of spec. Nothing was out and out fried, but they
were way out of tolerance. When pulling them out of the board, most of
them crumbled. I interpret this to be long term degradation due to heat
off of the tubes.

Anyway, in my case after replacing the resistors, I was back at a good
solid 100W with the same old same old tubes. I bring this up in the
context of Walt's question about how you decided your tubes were soft to
begin with... Might your "old" tubes have been solid and your r2-r5 have
been degraded? Perhaps also if your r2-r5 were degraded, then the hot
might have just pushed them over the edge. It will be very interesting
to see the results of your tests, please post them.

Subject: Re: [TS-520_820_530_830] ts-830S

Probably, one or more of your new tubes has a screen to control grid short.
This
placed high screen voltage on the control grid that should be biased near
cut off with negative voltage. When the filaments warmed, the tube started
conducting violently causing excessive current through the cathode resistors
R2, R3, R4, and R5.

These resistors serve as shunt resistors for the IP meter and also act as
fuses
in the event of a short like the one that happened to you.

You should replace R2, R3, R4, and R5.
Do not use resistors except 1/2 watt, the same wattage as the originals.
Do
NOT use larger resistors because they will not blow if needed and do major
damage if this were to happen again.

Also check R7, R8, and L2. R7 and R8 are 100 ohms 1/2 watt. L2 coil should
check 0 ohms. If it checks open, it is fried. Also look closely for cracks
or any indication that it is badly fried. If it looks like it has gotten
hot, not just dirt on it, it could be shorted.

Also check R1 100 ohms 1/2 watt and L1 choke coil. This chokes is checked
the same way as L2. Observe PS 1 and PS 2. These are two parasitic chokes
wound around a resistor. It is not likely that these were damaged and the
wire or the resistor inside will look like it has been overheated if they
are damaged. They may be covered. If so and the cover does not look burnt,
don't
worry about them for now.

After doing the above put your ORIGINAL tubes in and try again. After the
filaments warm up, key up in SSB with mike gain fully down and see if you
can set your bias control for 60 ma IP.

Let us know what happens. Even if the rig is now back to it's original
condition, get back with us.

I am interested as to why you concluded that the tubes were bad and what type and make the originals were. 6146 and S-2001 types do not go bad as often as the 6JS6 tubes in Yaesus do unless the rig has been hot rodded. I am not as familiar with the TS 830 as I am the 820, but screen supply problems can cause low output. I can help you check that.

Remember that the SG switch on the back has to be on. It often gets bumped while servicing.

To check the new tubes for shorts, check ohms between pin 3 and 5 with the tube removed. If it shows anything but an open, it is shorted. If it shows a very high resistance, like 100k ohms or more, check to be sure that your fingers are not touching the probes. Likely you will be measuring yourself.

With the bottom of the tube facing you, you will see a pin with a key along the side. This lines up with the key hole in the socket to establish tube rotation.

Still with the bottom facing you count clockwise from the key. The first pin clockwise from the key is pin 1 the last pin clockwise is pin 8.

Pin 3 is the screen grid and pin 5 is the control grid. These are the pins where the short will be.

If the tubes show a short, they are shorted. If they show a open, they may still be shorted and should be checked in a Tube Tester for shorts before trying them again. Do not be too quick to have a public hanging of the person who sold you these tubes. These grids can often short during shipment and handling. Some makes and types tend to do this more than others.

BTW, does everybody understand how a tube works basically?

Vy 73, Walt N9WB

Art:
Do you still have the mis matched pair? Have you tried them again? Since it held steady with them, it is more proof that the original finals were bad. Look at the mismatched pair carefully. Does the internal construction seem similar? If so they may be identical even though they have different brand names. I would put them back in and if they work I would check the neutralization and put it back together and go with it. Matched tubes is not super critical with parallel tubes. Very important with push pull linear RF and audio circuits.

6342. Re: [TS-520_820_530_830] MC-50(hi-Z setting) into a TS-820S

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-08 15:43:37 UTC
From: Dave and Loraine
Topic: 6342 Message: 6342

Happy new year to all.

Mic gain - I talk 4" from the mic but need the gain full-on to get correct ALC. (good audio
reports)

Compressor - The compressor gain is very low when CCW. Half-on it sounds bad and full-on, garbage.

Any suggestions welcome.
Cheers
Dave F4EYK

6343. Re: [TS-520_820_530_830] ts-830S

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-08 16:07:23 UTC
From: Arthur Petteway
Topic: 6299 Message: 6343

Hi Walt and the group, Yes the mixed brand 6146W tubes are back in the rig and are holding power around 95 watts. I am using the rig to make some rtty contacts in the round up today. I still think I will try and find some good 6146B tubes to see how they work in rig. My old 6146B's have to be weak.

Art:
Do you still have the mis matched pair? Have you tried them again? Since it held steady with them, it is more proof that the original finals were bad. Look at the mismatched pair carefully. Does the internal construction seem similar? If so they may be identical even though they have different brand names. I would put them back in and if they work I would check the neutralization and put it back together and go with it. Matched tubes is not super critical with parallel tubes. Very important with push pull linear RF and audio circuits.

> Hi Ron, Thanks for the information and interest. Well the reason I felt the 6146B tubes were bad is because I could key the rig and it would show over 100 watts and then the power would drop to around 85 watts and seem to stabilize there. I figured it was a final problem or the driver was bad. I put some old 6146W tubes which were different brands but they held the power out around 100 watts and did not lose power. So I figured I would order some new 6146W's because they seemed to work ok with just a little less power output. So we received the new GE/JAN 6146W tubes and a new 12BY7A driver and we installed them and that is when my problem started with the R2-R5 resistors. Those resistors failed when we turn on the heater switch. No load rig was in receive.So figure the new finals had a short but cannot find one with the ohm meter and that is how things stand at this point.Maybe next week we will be able to dig into the rig a little farther.

6344. Re: [TS-520_820_530_830] ts-830S

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-08 16:49:44 UTC
From: Walt Breining
Topic: 6299 Message: 6344

I was wondering how the tubes got weak. RTTY explains it. RTTY and slow scan are very hard on the rig as it is near 100% duty cycle.

vy 73, Walt N9WB

6345. Re: [TS-520_820_530_830] MC-50(hi-Z setting) into a TS-820S

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-08 16:58:38 UTC
From: Walt Breining
Topic: 6342 Message: 6345

The MC-50 needs to be worked close. You are correct to use the High Z setting. I never cared for the processor in the 820. However I find myself using during bad conditions. I run the compressor gain at about 10 o'clock. I used to use a home made compressor and EQ. I am presently building another one of a different design.

One symptom, if you get little or no ALC on 10 meters and more but still weak on 40 meters, the 12BY7 could be weak. Also not all 12BY7s work well. Toshiba and NEC work best. I used to use Sylvania but I would take a couple of boxes of them and find the best one. I used to be in the service business. The ones I did not use, worked fine in everything except Kenwoods and Yaesus.

I assume you are peaking the drive control for max with meter in ALC.

I think your problem is that you are not working the mike close.

Vy 73, Walt N9WB
Good audio is an Amateur Radio tradition, not a crime.

6346. Ready For First TS-830 Mod

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-08 22:45:48 UTC
From: Kevin der Kinderen
Topic: 6346 Message: 6346

I have held off doing any modifications to my 830 (I LOVE THIS RIG!) but I think it's time to do the filter mod. I'd like to be able to use the narrow filters for PSK.

I've found the documentation for the mod. I just wanted to know if anyone here has performed this mod and found any problems or have any hints for me. Has there been any problems using it with PSK in USB?

Speaking of PSK... the 830 has been doing a great job for me. The best IMD I can get (as read on my KK7UQ IMD Meter) is -28. That's good, but I'd prefer to be down around -30 or better. I've tweaked about everything but seem to have topped out at -28. If anyone with an 830 is considering the digital modes, the rig works great. With the external VFO, I've never had a report of drifting. Never tried the internal VFO for that though.

73,
Kevin - K4VD

Hi Kevin, I have the TS-830S and did the filter mod a few years ago and it works FB on usb or lsb. I used the DH switch to change the filter off or on because it is located in an easy to use location. As far as drift my 830 after warm up is plenty stable to work psk. We work psk all the time and most of the other modes that work with a sound card. The cw filter that I have is the 500hz and using it plus the if shift and vbt you can really bring the filter edges to where you need it on most modes. Have fun and good luck with the mod.

Walt, Most of my contacts are on PSK, RTTY and some of the other sound card modes. I add in a little of CW and SSB. We run the rig in the digital modes below 50% of full output. TS-830S seems to work FB at that power level.

I was wondering how the tubes got weak. RTTY explains it. RTTY and slow scan are very hard on the rig as it is near 100% duty cycle.

> Hi Walt and the group, Yes the mixed brand 6146W tubes are back in the rig and are holding power around 95 watts. I am using the rig to make some rtty contacts in the round up today. I still think I will try and find some good 6146B tubes to see how they work in rig. My old 6146B's have to be weak.

Thanks Art... I remember seeing where someone had used the DH switch
but forgot about that. Seems like a perfect use for a switch that has
apaprently no other use.

Good to know about the internal VFO. I'm going to have to run it for
my next few QSOs and see how that goes.

Maybe next weekend I'll tackle the filter mod and will post the results.

73,
Kevin - K4VD

Hey Kevin, where did you get the info on this mod? (I love this rig too!!!) And I'm moving towards setting it up for digital modes.

Thanks Art... I remember seeing where someone had used the DH switch but forgot about that. Seems like a perfect use for a switch that has apaprently no other use.

Good to know about the internal VFO. I'm going to have to run it for my next few QSOs and see how that goes.

Maybe next weekend I'll tackle the filter mod and will post the results.

> Hi Kevin, I have the TS-830S and did the filter mod a few years ago and it works FB on usb or lsb. I used the DH switch to change the filter off or on because it is located in an easy to use location. As far as drift my 830 after warm up is plenty stable to work psk. We work psk all the time and most of the other modes that work with a sound card. The cw filter that I have is the 500hz and using it plus the if shift and vbt you can really bring the filter edges to where you need it on most modes. Have fun and good luck with the mod.

Ron:

The filter mod can be found here.

http://www.mods.dk/view.php?ArticleId=788

I'm using the SignaLink. Tigertronics provides a cable to connect to the mic jack. I have the external speaker and use the line-out on the speaker for audio back to the computer. The setup works OK. I have to keep the volume pretty low so I don't overdrive the sound card.

Good luck on getting the 830 on PSK. Let me know when you have it and maybe we can hook up for some testing.

Kevin, thanks. I'm also looking at getting one of those Tigertronics interfaces, basically I will have the same set up that you have. Do you have the SL-1 or the 1+ unit? In other words, are you using the remote jack on the back of your 830, or are you using the mic? I want to keep my microphone hooked up.

Topic: 6308 Message: 6353

I think the failures of new tubes have more to do with
the way they are shipped than the manufacture or
vintage.

I have received tubes packed in not much more than
their original boxes; no room for shock absorbtion
when the box is thrown or dropped.

When I ship tubes I put them in bubble wrap, then at
least 3" of foam peanuts, then a good box. Never had a
failure reported.

The unit I have is the SL-1+. The cable that came with it uses the mic
jack on the front. I didn't know there was any place on the back for
audio in. It will need PTT also. I'll have to check into that.

Hi Kevin. Well, I wrote the previous message while I was at work, and I am now looking at both the tigertronics webpage and the 830 manual. The SL-1+ says it can be shipped with a 8 pin din connector, and it says specifically that you can jumper the cable however you need it for your rig. At work I was thinking that the remote or xverter din plugs on the back of the 830 could be used. Looks like I was half right. You can key the rig on the remote plug, but I'm not seeing any place to send audio in. The manual even says that if you want an auxiliary audio in for a phone patch like the 820 has, you have to wire an additional plug. Oh well! That just means I can go ahead and buy the cheaper SL-1 instead of the 1+.

6357. Re: R2-R5 Failure

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-10 04:27:47 UTC
From: Larry
Topic: 6308 Message: 6357

My tubes arrived packe the same way. Here's my story:

I received 2 new 6146W's from (a place in Nebraska) tonight, and stuck them in the 820S. let it warm up, then hit the send switch to check idle current. It was a bit high, then OH NO! a spark from the tube section. I immediately turned off the unit, and pulled the cover. Couldn't really see any problem, so tried it again, with the same results. Couldn't tell exactly where the spark came from, but this time the IP pegged, and the cathode resistors are fried. could I have the exact same problem as Art?

I ohmed out the tube pins, and nothing shows shorted that isn't supposed to be.

I can't go any further until I get some new cathode resistors.

6358. R10 Value?

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-10 04:51:41 UTC
From: Bill Scurlock
Topic: 6358 Message: 6358

To "The Group",

I'm chasing confusing documentation for the TS-830 Final Unit (X56-1380-00; J25-2772-03). The Ip metering voltage divider, R6 - R10, has inconsistent documented values. R6 is always shown as 2700 ohms, and mine measures 2663 ohms so is probably ok. However, R10 is another story. My revised edition service manual shows R10 to be 10,000 ohms. A schematic I downloaded from the internet shows R10 to be 4700 ohms. The R10 actually installed in my radio shows to be 6800 ohms (measures 6898). All of these claim to be for the X56-1380-00 final unit. So I am confused as to the correct value for R10. I re-measured the cathode resistance again and it is still 5.06 ohms which is fine. I don't think any of this affects the somewhat low power output I'm chasing - I just wanted to know if my metering was accurate. These different values of R10 could certainly change the Ip meter indication. Does anybody out there know the correct value for R10? Thanks.

73, Bill, K5GCW

Larry, if your 820S uses the same four 20 ohm 1/2 watt resistors to obtain a cathode resistance of 5 ohms at 2 watts, I replaced mine in my 830S with two 10 ohm 1 watt resistors from my local Radio Shack. Others have told me that they did the same thing with good results.

Also, someone in this group posted sources for the 20 ohm 1/2 watt resistors a couple of days ago. Good Luck.

73, Bill, K5GCW

Topic: 6346 Message: 6360

You'll have to let me know how it turns out. I discovered something new about the SL-1+ today that I didn't know it did...

I send audio and ptt to the rig through the mic jack on the front. For receive audio, I was taking the line out of the external speaker and running it direct to the computer - no isolation.

I didn't know this, but on the back of the SL-1+ (and SL-1 maybe?) there is a separate speaker jack. I was able to run the line out from the speaker to that jack and then a separate cable down to the computer. So now the SL-1 is providing isolation on that side... I think. I didn't notice any difference in performance, but a little more piece of mind.

6361. Re: [TS-520_820_530_830] Low power 830s R10 Value?

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-10 13:04:46 UTC
From: Walt Breining
Topic: 6361 Message: 6361

BTW, did I tell everybody to check R 14 and be sure it is 1 K. This is on the Rectifier unit board. If this were high in value, it could cause low power.

Hummm
My diagram shows 10K but it is just a print that I got off of the web so I don't think it possesses any particular magic. I would guess that perhaps there were different meters used in some productions and I would use the value originally on the board unless you think it might have been changed.

Subject: [TS-520_820_530_830] R10 Value?

> To "The Group",
>
> I'm chasing confusing documentation for the TS-830 Final Unit (X56-1380-00; J25-2772-03). The Ip metering voltage divider, R6 - R10, has inconsistent documented values. R6 is always shown as 2700 ohms, and mine measures 2663 ohms so is probably ok. However, R10 is another story. My revised edition service manual shows R10 to be 10,000 ohms. A schematic I downloaded from the internet shows R10 to be 4700 ohms. The R10 actually installed in my radio shows to be 6800 ohms (measures 6898). All of these claim to be for the X56-1380-00 final unit. So I am confused as to the correct value for R10. I re-measured the cathode resistance again and it is still 5.06 ohms which is fine. I don't think any of this affects the somewhat low power output I'm chasing - I just wanted to know if my metering was accurate. These different values of R10 could certainly change the Ip meter indication. Does anybody out there know the correct value for R10? Thanks.

Any sparking in the tubes, or spiking of plate current
with new tubes, you should do just what you did, shut
down immediately.

I have seen tubes clear a short, about 50 percent of
the time the arc once and that's it; but it's risky to
try this.

I guess the key, given the present state of supply of
tubes, is to be able to fix whatever a bad tube might
blow up in the rig and move on to another pair.

I think there were production changes to perhaps
'accurize" the plate current meter a bit.

Actually, the 820 uses two 10 ohm, 1 watters, so the Radio Shack resistors should work fine. Ron (KC0TLN) has offered 4 of his 20 ohm resistors to tide me over until I can get some of my own.
I checked the Radio Shack web site, and they didn't show the 10 ohm 1 watters, so thanks for the heads up!

6365. Re: [TS-520_820_530_830] Re: R2-R5 Failure

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-10 21:05:53 UTC
From: Arthur Petteway
Topic: 6308 Message: 6365

Hi Larry and the group, Well Larry you have the exact problem I have with the tubes from Nebraska. The tube I am talking about is the GE/JAN 6146W which is probably the same tube you got. Larry please e-mail me direct at wb4mnk@... because I need to ask you something.

73
Art

Subject: [TS-520_820_530_830] Re: R2-R5 Failure

My tubes arrived packe the same way. Here's my story:

I received 2 new 6146W's from (a place in Nebraska) tonight, and stuck them in the 820S. let it warm up, then hit the send switch to check idle current. It was a bit high, then OH NO! a spark from the tube section. I immediately turned off the unit, and pulled the cover. Couldn't really see any problem, so tried it again, with the same results. Couldn't tell exactly where the spark came from, but this time the IP pegged, and the cathode resistors are fried. could I have the exact same problem as Art?

I ohmed out the tube pins, and nothing shows shorted that isn't supposed to be.

I can't go any further until I get some new cathode resistors.

Larry

It is a good practice, when getting tubes being shipped in a manner other than their standup position, is to place them in the sockets for a bit with no power and let the elements settle in. Sometimes the filiments sag. Just a thought....Brad KB2CHY
Quoting Bill K0ZL <coorsbill@...>:

I always test tubes that I buy from where-ever in a tube tester before sticking them in a rig. Saves the pain.

Goog advice, but I have yet to find anyone that has a tube tester
that will test the 6146's.

I'm still looking though.

Don't look for tube testers from the 40's or early 50's. Many of the
"better" testers from the middle to late 60's and 70's will test 6146's.
My Hickok 800 and 6000 and Sencore "Mighty Mite" all test 6146's. Several
of the B&K and Heathkit models also test them. I never stick any tube,
whether I bought it or it came out my own tube stash, in a rig until I
first run it in a tube tester. Nothing is more frustrating then sticking
in a replacement tube and then watching something else go up in smoke.

Hi all, this seems like a great group. I picked up a TS-830S up for a back-up to my IC-746 Pro. I like the old Kenwood very much. I was wondering if anyone has done the slow tune mod on the VFO-230. I did the mod and now it will not except anything into memory. I cut D19 D20 D22 D23 D24 D26. The mod works great as far as tuning goes.
(I have been using the 830 more than the icom)
Thanks
73 Terry

I also did the mod and double checked it before I performed the cuts. Wound up having to have it but back together because it messed up the optical assembly calibration. After all the work I decided it was not worth it. I have seen some that worked and some more that failed.

6373. VFO-230 Problem

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-11 22:14:06 UTC
From: davewalinski
Topic: 6373 Message: 6373

I have a VFO-230 that works just fine from a cold start. 25 Khz per turn. But when warmed up only 4 or 5 Khz per turn. Have to turn the knob many more times then normal to get 25 Khz.Just not linear when turning knob. I could move the knob extremley slow and the frequency would not change at all. Something must be breaking down after getting warm. Any Ideas? It does not have the mod done to it as far as I know. Thanks.

6374. New TS-830S owner with a receive problem

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-12 07:41:00 UTC
From: danceswithtransistors
Topic: 6374 Message: 6374

Hi! I just bought a TS-830S on eBay. I got it for a discount because of a receive problem. I measured 100 watts into a dummy load in CW mode. That seems to be a typical output. So, I guess the transmit part works.

The receiver section is seriously hosed, though. It makes this God-awful noise every 25 kHz or so. The noise changes pitch like a slide whistle as you tune. There is a faint echo of this noise midway between the main occurances.

Does anyone have an idea of what the problem is?

I want to fix this myself. I haven't done anything like this in twenty years. My neighbor has a garage full of test equipment. I don't know how it will do at RF frequencies, though. The o-scope maxes out at 5 Mhz or so. The hardware guys at work said that I could borrow test equipment on the weekend if I want to.

Any help in getting me started would be greatly appreciated.

Thanks.

Mike

Mike,

Is it possible that the calibrator is turned on? Check the mic gain
control. If it is turned fully counter clockwise the 25KHZ calibrator
will be activated. It will generate a signal every 25KHZ across every
band.

The crystal calibrator may be "on"..... Turn that "off". Then see what happens....

Sounds like the marker generator (if I recall what it is called correctly)
is turned on. Is the MIC control set to CAL ? If so turn it to off.

I was wondering with all problems with the 6146W tubes from Nebraska , means maybe that we should not use them. I also have just purchased a new matched JAN 6146W pair from Nebraska but I am afraid to use them now in my TS 820s.

Regards
Mark

6381. Re: R2-R5 Failure

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-12 23:50:49 UTC
From: Rick
Topic: 6308 Message: 6381

I have used (and fitted in others rigs) 6146w valves to several Kenwood transceivers over the last ten years or so. My understanding is that providing the radio was designed to use 6146B's, then 6146A or 6146W are OK. The file (on this website) regarding the 6146 family makes this very clear. I am currently using NOS 6146W's from Surplus Sales, Nebraska. The term, ruggedized or military version, often used about the 6146W, refers to it's mechanical construction. It may therefore better survive the postal service!
Cheers
Rick VK4NR (ex VK7RL)

Ken:

Thanks from here. I called the Shure folks two or three times and all I was able to locate from them and my own search....it has been a while....maybe been updated......was the 444 D microphone....which is somewhat of a different animal....

Your link took me to what I have been looking for quite a while...as I have the vanilla 444 that I bought new a very long time ago. Did you do the speech proc mod???....I haven't and have always been told to turn it off...so my guess is that it makes a difference.

Everyone also says the 718 Icom I also run gets thru better running the proc at 50%....so I have some valid homework to get going on now.

Thank you

Glad to help!

No, I haven't done the proc mod. I usually don't run a compressor on any of my rigs except the IC-706MkIIG I use in the car and it is set rather low. Since I'm only running 100W in the car the extra "punch" is somewhat helpful. At the base station, however, even with a 100W barefoot rig I rarely use compression because it restricts the audio so much. It is OK for a short DX contact exchange but not for rag chewing. Your buddies will be very unhappy listening to you! That is probably why they tell you turn it off! :)

Welcome Trace:

One item left out is to find out what ham candy stores are in your area in addition to clubs. They are usually staffed by hams and will help guide you in purchasing accesories. Nearly every one of them I have dealt with are not high pressure to make you buy something you do not need. They are a good place to start for a lot of accesories before taking a chance on "Bargains at hamfests and online sales" until becoming acclimated to that environment. When you get your license, they will also let you play with live gear!

The 820 is a great rig and I love the one I have...It does not have a built in SWR meter. If you build single band dipoles, you may only need a meter....to crop your antennas to the right operating freq. Always build long when you do not have a tuner and only a meter.

Ham stores also sell pre-built wire antennas, and eham.net is one of several places you can research for customer satisfaction for a lot of ham products, new, old, and very old.

If you want to run multi-bands like a G5RV or others...you will need a tuner....Then you have to decide auto tuner or manual...Mine is Manual...but auto prices have come down for low power rigs lately, so if I had to do it again I may auto....they vary wildly in results, so research if you go that way....

If you think you might want big power later install big coax now. If not, install low loss small coax. Small coax will have a bit of power waste, but there are varying qualities and losses in that arena. Again do your homework on small coax if you go that route.

Use good "ham rated rope" to hang wire antennas...well worth a very small extra cost. I re-hung my G5 multi band antenna 3 times in less than two years with big but rot prone material. After changing, it has been up over two years and still holding up well.

You can homebrew an antenna hanger for under $20 U.S. with a low end fishing reel and a sling-shot and hit branches 50 feet high (That's 15 meters or so). It works, I have a picture on either here or the amateur repair group page on what it looks like.

Again, as others have stated, if you can find a local club, join, as you will find others, who may show you around the ham bands, and sit in their shack, so that you can find what your operating preferences for what bands you grow to like may be.

You will get plenty of help here from a lot of good people in your Kenwood endevors...and thank you for serving our country!

Thank You. Now if we could convert it into a form that we could place in
the files or pictures section of this and the KenwoodMics group.

Vy 73, Walt N9WB
Good audio is an Amateur Radio tradition, not a crime.

6387. Re: [TS-520_820_530_830] Re: R2-R5 Failure

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-13 10:08:38 UTC
From: Richard Harris
Topic: 6308 Message: 6387

What anode voltage were the tubes tested at? From the data sheet, the
maximum anode voltage of the 6146W is 600V for standard commercial service
and 750V is permitted for Amateur service. The Kenwood rigs use 800V.
Perhaps the tube tester used 600V.

Hold off changing as long as possible!

From: Walt Breining
Topic: 6308 Message: 6388

The tester probably used 150 to 200 v. That would show a short but not a high voltage arc. As I've always said, if a tube checker shows a tube is bad it usually is. If it shows that the tube is good it might be.

Good point Richard.

Vy 73, Walt N9WB
Good audio is an Amateur Radio tradition, not a crime.

6389. Re: [TS-520_820_530_830] MC-50(hi-Z setting) into a TS-820S

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-13 14:05:11 UTC
From: Dave and Loraine
Topic: 6342 Message: 6389

Hi Walt,
Thanks for the good advice
No problem found with the driver test.
With the 'toilet-roll' mod, close-talk and 60% mic gain, the ALC is OK.
I'm comfortable with 4" distance and the mic mod using full mic gain.
Next time I lift the hood, I'll check the mic amp voltages and tweak the processor RF slugs for
best quality.
Thanks again
Dave F4EYK

6390. Differently coloured Frequency Selector and Make\Model Badge

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-13 14:55:04 UTC
From: M0GSM
Topic: 6390 Message: 6390

Hi,

A quick question....

Have had 2 830s in my time. The second one has a different coloured frequency selector. Unlike the first 830 which matchs the colour of the rig i.e olive green(ish) with silver centre, and the frequency markings aree green on white.

This second one has a darker green selector with a off silver/white metallic centre, and frequency marking are white on a dark green background. Also the model badge 'Trio 830S' is bronze as oppose to silver on my first rig.

I was thinking the the frequency selector has been replaced but the the frequency marking match the dial(it looks like the original), and the name plate is matching i.e not silver but bronzy\green colour.

What does this tell me about the rig. Is it a later model or something?

Dave

Walt:

I'm better at computers than radios and I have done the transition before, but has been awhile. Adobe does like you changing their stuff.

Will try to figure this one out.

6393. New Member/Hello Kenwood Group!

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-13 16:26:11 UTC
From: wb5dx
Topic: 6393 Message: 6393

Hello - I have just joined to learn a bit about the 830 and the 530. I don't yet own one. But, my plan is to get either model for a couple of reasons. I have been moderately active in recent years (after a long abscence) but have ony "operated" solid state equipment. I have also forgotten more than I acutally knew in part because I just can't work on my current equipment! I have always admired the 830/ 530 line, I thought I could aquire one to enjoy and to provide a way to bring back some of the lost knowledge as they seem to be a bit more service friendly (better than a 756Pro, etc).

Which would be the better choice - the 830 or 530? I have been watching Ebay and the prices seem a bit high. Is that the best source? Should I get a dead one and learn more by rebuilding or get a reburbished one and maintain - or some where in between? Any known dealers to be concerned about (good/bad, etc). What are the price ranges that could be expected?

There certainly seems to be an incredible wealth of knowledge on this forum (and patience!), so I thought this would be a good place to start.

Thanks for any help.

73,

Bill

At this point, since they tested good on the tube tester, I have no way to prove that the tube(s) are bad, The only thing I can do is try them in the unit again.

You could always get a lemon from any source, but generally speaking, a
better rig can be had for less money from qth.com, qrz.com, eham.net etc.
than ebay. Good 830s usually go for around $400.

when turned on (pwr&htr sw)it seems to take longer than it used to before i can get a meter reading for peaking drive. place in send, and adjust car has no affect. it's intermintant, and after a few min of messing with drive, it starts giving up some power. once i get it going it's fine on all retunes. does this sound like something going bad (6by7 or other)????

Most tube testers use very small Anode voltages. The tv7 I used
probably tests at less than 200 volts. http://www.jvgavila.com/tv7.htm
that's one reason the tube tester isn't the final answer.

A new driver tube (12BY7A) would be the place to start because it is easy
to change. Can you get ALC indication on all bands, CW, key down, driver
peaked, carrier level at max? On my 530SP I get at least half scale on
most bands with the level control set to half way.

I understand that the driver tube does not last as long as the PA tubes.

6399. TS830s Duty cycle problems

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-13 19:31:26 UTC
From: KI4BUN / AAV4TP
Topic: 6399 Message: 6399

Greetings,

I have a TS-830s which has new power supply caps and new 6146W's installed.

The other night I was passing a piece of traffic on an Army MARS net and after about a minute of transmitting: my fuse blew. I was running about 100 watts at a 1.5:1 SWR into a verticle dipole Gap Titan.

This has become a problem, as it isn't the first time. It only happens after a period of time with the rig keyed. It takes a minute or minute and a half of transmitting to blow the fuse. Short transmissions are fine.

I'm stumped. Any suggestions?

Thanks!

73

Chris AAV4TP/KI4BUN

Hi Bill:

I'm an 830 owner and I have enjoyed this rig for all modes CW and Digital. I don't do much voice but have gotten great reports from it.

First... I'd not recommend a dead rig. Maybe a good rig now and a dead rig later for playing around with, spare parts or maybe even a backup.

I have had mixed luck on Ebay. I use QTH.com and eHam.net classifieds. I much prefer working with hams and even talking to them on the phone before finalizing the deal.

There are 830s and 530s out there that are in a good a shape as when they were new. I paid about $800 for my setup but that included the external VFO, tuner, speaker, monitor scope and phone patch. I believe you can search the classifieds mentioned above for old posts to get a feel for how much the sold for in the past.

Finally (I think I'm right about this), there is no difference between a "Gold Label" 830 and any other 830 yet some people mention it as a selling point. Look what the average price of an 830 (or 530) is going for and don't pay more for a gold edition.

I think you are in the right place with this group for good advice before and after the purchase. If I'm wrong on anything above, someone will chime in.

73,
Kevin - K4VD

> Hello - I have just joined to learn a bit about the 830 and the 530. I don't yet own one. But, my plan is to get either model for a couple of reasons. I have been moderately active in recent years (after a long abscence) but have ony "operated" solid state equipment. I have also forgotten more than I acutally knew in part because I just can't work on my current equipment! I have always admired the 830/ 530 line, I thought I could aquire one to enjoy and to provide a way to bring back some of the lost knowledge as they seem to be a bit more service friendly (better than a 756Pro, etc).
>
> Which would be the better choice - the 830 or 530? I have been watching Ebay and the prices seem a bit high. Is that the best source? Should I get a dead one and learn more by rebuilding or get a reburbished one and maintain - or some where in between? Any known dealers to be concerned about (good/bad, etc). What are the price ranges that could be expected?

no alc reading, or touchy reading until it warms up. band or car level does'nt matter. sometimes it shows half scale for a sec, then down to nothing for a sec, then after awhile it smooths out.

6402. TS-830S Low Plate Current

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-14 00:09:46 UTC
From: Mark
Topic: 6402 Message: 6402

Hello,

Last weekend, I was operating in the RTTY contest (running about 40 watt, in the last half hour of the contest, all of a sudden, I noticed that I could get no more than 10 watts SSB or 30 watts CW out of the Rig. I checked the cathode resistors and I am get 5.1ohms. I had a new pair of 6146W's and a 12BY7A that I put in the rig, but got no output what so ever. SG Switch is on. I put the old set of tubes back in, and I am also now getting no output on them. I have a 60ma idle current and I can run the grid bias all the way up through the bias knob on the back. HV is 800v+. In Tune mode, I have no plate current, and in CW mode, I get around 60ma, but no RF at all. Any suggestions?

Thanks,

Mark, K9MQ

6403. KB-1 vs the standard tuning knob

Hello all!

I joined this group after reading a recommendation in QRZ.COM that it was very knowlegable about Hybrid problems, I hope so!

After getting my Novice back in 1980, stationed on Guam (USN), I never used it. Many years later I decided to upgrade and get into Ham again, got my General and NEVER USED IT!

Not long ago, I started working for Harris RF, and it woke my interest again, so I jumped on E-Bay and bought one of the very same rigs that I was originally drooling over! What a find! Good thing I kept renewing my ticket during the past few decades.

Damn thing dont work....

Im sure you all have seen this before, but here are the symptoms:

Receive functions good.

Transmit: IP at 60 ma
HV at 800

When attempting to tune in TUN, no ALC when send depressed, no RF output. (Using SWR/PWR meter & 100W dummy load)

Reading all I could, I decided the 12by7a was a goner, ordered and replaced ALL tubes as the finals were S2001A's. Symptoms the same.

The ALC does not swing on any freq, but the instant the send key is released, it will swing a part ways up the scale and settle back to zero. The amount of Mic gain does seem to determine how far up it swings before settling down again. Mic/Car gain have been set about the 10 o'clock position.

It appears the finals are warming, and I get a nice 'ZAP' when grounding them out, so the are getting power. Once during playing, the rear final let out a small flash of light. Arcing? No where to dump the HV present? Hmmm.. you can tune a radio, but you cant tuna fish..

Hope someone can help. Looking forward to chatting, thanks!

Brian

Yes it is. I tried to eliminate the common sense problems and read
alot about troubleshooting for a week or so now, but have not seen
this particular problem mentioned, but thanks, yes I did check the
switch, hopefully it is functioning ok. The Unit is quite clean inside
with no signs of repair, I dont believe it has a whole lot of hourse
on it (Hence the s2001a finals found inside).

Hi Chris..and welcome aboard!

I know it could be something really basic, but it happened to me on my 520. Check the manual for the proper fuse VALUE. I ran into the problem of putting the 1/2 rated fuse in place of the proper one, before I realized that basic difference in 120 volt vs 240 volt operation. Made a ton of improvement, with a minimum of effort. And, I **KNOW** that I am not the first to run across this! :P

73s..and good luck!

Hi all,

I have been using my TS-520 and I am very happy with it. Now I would like to try PSK31 and another modes (SSTV...). How to interconnect my TS-520 and soundcard on my laptop? And can I use rear rounded 8pin REMOTE connector or only MIC in front of the panel? Great many thanks for advices.

Ivo

Turn the carrier control fully up. Place the meter switch on ALC. Key rig on tune and see if you can peak the drive for max on the ALC meter. If so then peak plate and load on your watt meter. Be sure that there is nothing plugged into the key jack in the back.

Some versions of these had some transverter switches on the back. be sure that they are working properly.

Turn the mike gain to 1 or 2 o'clock. Key up on SSB. Go ahhhh into the mike and peak the drive, plate, and load for max output on your watt meter if you can get an indication.

These are both fine rigs. As with any rig, these have some weak spots. They have band switch problems. There is a coupling shaft in the back that breaks and is fairly easy to replace. If your coupling is good, lubricating the bushings on the part behind it will reduce stress. Use a drop of Mobile 1. as recommended by K0ZL. Lubricate the other bushings while you are at it.

The other problem is that bandswitch wafer contacts are riveted to terminals on the bandswitch wafers. In time expansion and contraction makes these connections intermittent. The solution is to solder the contact, terminal and rivet together on each contact. While this takes patience it is doable and will result in having one of the finest rigs ever made.

The 830 is the best of the two. It is one of the finest transceivers ever made except for some of the most expensive modern digital surface mount stuff. It's receiver is superior however the 530 is also quite good.

> Hello - I have just joined to learn a bit about the 830 and the 530. I don't yet own one. But, my plan is to get either model for a couple of reasons. I have been moderately active in recent years (after a long abscence) but have ony "operated" solid state equipment. I have also forgotten more than I acutally knew in part because I just can't work on my current equipment! I have always admired the 830/ 530 line, I thought I could aquire one to enjoy and to provide a way to bring back some of the lost knowledge as they seem to be a bit more service friendly (better than a 756Pro, etc).
>
> Which would be the better choice - the 830 or 530? I have been watching Ebay and the prices seem a bit high. Is that the best source? Should I get a dead one and learn more by rebuilding or get a reburbished one and maintain - or some where in between? Any known dealers to be concerned about (good/bad, etc). What are the price ranges that could be expected?
>

Topic: 6399 Message: 6413

I assume that you were running SSB. for 117 v operation, the fuse should be a 6a fast blow type. For 234 volt operation it should be 4 amp. If you are running on 234 V please note that the rig is set up for 220 not 234 and some taps need to be changed or it may take off and blow fuses.

Be sure that your idle current is no more than 60 ma. Be sure that the plate tune is peaked for maximum output or minimum plate current.

I assume that you are running SSB. For RTTY output should be no more than 20 watts because RTTY is 100% duty cycle. The RTTY output can be reduced by reducing the mike gain.

It is also possible that your final tubes are arcing over. There seems to be a lot of this going around lately with 6146W's.

You might also check your neutralization although I doubt if this is likely to be the problem on 80 meters.

Depends upon what rig. I got one for my 820 and it looked funny. I liked the feel though. It looks better on the 530/830. It got damaged, "long story" and I am now using the standard chrome front knob.

I understand the KB-1 is going for the price of a rig these days!

I can't help but wonder if fishing weights could not be glued inside the basic knob evenly near the outside. Maybe use hot glue so it can be removed if the project became a Murphy's Law special.

Gave it a try again, but no ALC deflection until send released as before. So far, I have checked all switches and variable resistors associated with tuning. Checked the cathode resistors and compared Q10 to another transistor of the same type, all seem ok. Ive carefully inspected all boards and connections and the unit seems very sound and no overheated resistors. When I got it, the bottom side standoff was stripped, and I had to carefully bend the bottom cover to get a wrench in there to get the bottom center screw out, I dont think anyone has opened the bottom up in a LONNNGG time.

I dont know what to check next im afraid, information for troubleshooting is limited on the internet and Ive ordered the schematics for it. Paying someone to fix it would cost as much as I paid for the unit I bet, ouch, cant afford that...Id rather save up and spend the money on a second, quaranteed operational unit and just compare readings between the two units.

Didnt mean to write a novel, im a fast typer :)

thanks Walt

Ok, rechecked all front/back switches, set up per operating manual and tried again. No ALC. turned up the CAR and hit send, saw a arc from finals area. Checked finals and turned on power again, no glow from rear tube, but front tube glowing very hot? Shut down, let cool, put old tube back in rear slot, turned on. No heater glow from front tube, old tube heating as normal. No ALC. Looks like I blew both the new 6146W tubes now and still have no clue to problem.

I cant afford this...time to cut my loses and sell on E-bay cheap. But I will let buyer know and not screw THEM over.

Thanks for the help, back to computer games.

I filled my original 830 knob 15 to 20 years ago with lead shot. Glued it in place with epoxy. Kept the openings clear to get at the set screws. I think I used a Q-tip stick. After the epoxy had hardened, removed the stick. Gives a nice feel when tuning the rig. Can't remember where I got the lead shot from.

6422. Praise for the TS-830S

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-15 01:52:29 UTC
From: Hauser, Ron M.
Topic: 6422 Message: 6422

Well, I have a TS-830 that I have been fixing up, and I have been impressed with it. Today though, I spent some time on the NA QSO party, and I am realizing just how really fine this radio is! The CW filter plus the variable passband tuning make tuning around on a crowded band a complete breeze.

Now I just have to fix that S meter and the wierdness on 30m. :)

6423. TS-530S, receive poor, no tx

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-15 03:56:27 UTC
From: carboyhat@juno.com
Topic: 6423 Message: 6423

The receiver is really weak sounding. I have to hold the top cover with the speaker up to my ear to hear anything, even with the audio gain up all the way. The RF gain control does not affect signal strength, however the attenuator will reduce the signal. The drive control does peak signals.

The transmitter has 60 ma. resting plate current, almost 900 volts on the HV scale, but in TUNE, I get no ALC reading. All three tubes light.

I am trying to find something common to both of these problems. Looking at the schematic, if L41 were shorted (primary to secondary from a nearby lightning strike) that would reduce the sensitivity but not affect transmit. I will take the driver tube out of a working 830S and try that for the transmitter. Maybe the rig has several unrelated problem areas that happened to manifest themselves at the same time.

The problems exhibited themselves after the rig was turned on. It worked fine the week before.

Anyone been here before?

Bob, AA4AI

6424. Hand mic for an 830

Yahoo group: TS-520_820_530_830 (2006)

Also, I may have possibility of obtaining an MC42s. Does anyone know
the wiring to covert the 8 pin to the required 4 pin? Thanks - Bill

6426. Re: [TS-520_820_530_830] Re: Hand mic for an 830/MC-42

Yahoo group: TS-520_820_530_830 (2006)

Topic: 6424 Message: 6426

Bill,

Here is the Kenwood 8 pin mic plug wiring:
1- mic hi
2- PTT
3- frequency down
4- frequency up
5- +8VDC
6- n/c
7- mic lo (shield)
8- PTT ground

Here is the Kenwood 4 pin mic plug wiring:
1- mic hi
2- PTT
3- PTT ground
4- mic lo (shield)

Good luck with the '830! Now start looking for the VFO-230. :)

Morning Bob;
I had the same thing with my 530S, one day it worked fine, the
next there was hardly any audio. Funny you should mention the
lightning strike, here in Long Island, this time of the year, that
was unheard of, that has since changed, but between the time the
radio worked and when it lost audio we had lightning, not near by
that I know of. Same symptoms, tuned up just fine, the meter worked
fine in the tune up,regular power out but no deflection on the meter
in receive at all. The only time I saw movement was when my next
door neighbor came on the air and even then the audio wasn't that

great. I took a quick look but decided to send the radio out for service, I've had it since it first came out, sorry I can't offer more. John K2IZ

I'd check the power supplies first. make sure all the voltages are
within specs, not just the HV.

I'm not sure what your problem is. Do you have access to an
Oscilloscope? The next step would be to check for RF drive, all the
way through the RF path.

I do have one question, were the new tubes, particularly the one
that arced, 6146W's?

> that arced, 6146W's?

Larry,

No o'scope at home, just a DMM, just started trying to put a shack
together with limited funds.

To recap:

From the original symptoms, I guessed the driver was bad, so ordered
and replaced all tubes, 12by7a and replaced finals with 6146w's as I
read they were more robust than standards and read all tubes should be

replaced at once.

After the rear tube arced, I shut it down, and wrote an email here. Later I tried again with MIC turned up as mentioned in a response, but rear tube was dead, and front tube began to glow red. Shut it down. Put old tube (s2001a) back in rear, powered up, and old tube heated, but new tube now dead in front.

I think I shall put this rig away until I can either buy a working rig to compare it to for troubleshooting or find someone in the local area willing to work on it for a reasonable price. Im new to the region and dont know anyone here yet. (Rochester NY area)

I have schematics (User manual) on order, and I will keep my eyes open for a older o'scope, sig gen and whatnot...but all this will take a while to do. Guess I just have to be patient!

Thanks Larry.

6431. Hi from Jim ve4ags

Part of your problem may be that you are dealing with some bad NOS
6146W's. Two of us on this releflector have purchased the 6146w's
from a place in Nebraska, and we both had arcing problems.

6435. What is the best choice

Yahoo group: TS-520_820_530_830 (2006)

Larry, I think that you have two problems. The rig didn't work and you thought it might be the tubes so you replaced the tubes with bad ones. (through no fault of yours of course).

So we are back to the following, No ALC on CW or tune, No ALC while going ahhh into the microphone with the mike gain all the way up.

Now where I have lost track is how is the receive?

Does the 12BY7 Light? You can leave the finals out for now. Turn the SG switch off while the finals are out. Be sure the plate connections in the final section are positioned such as that they do not get into mischief.

N9WB Walt

Topic: 6404 Message: 6437

Another thing:

With the bottom of the rig up and the rear facing you, find the 120/220 switch on the back. Just forward and to the left a bit is a metal shield or wall around the HV boards. Near the 120/220 switch there are a lot of wires grounded to this shield or wall through a hole on the edge and soldered. These solder connections are often bad. Check this closely. They may seem solid, but may be connected by flux. You may want to remove these wires and re dress them, clean the metal well and resolder them well.

Anybody working on a 520 should check this.

BTW, I think that there is a good possibility that when you get the other problems solved, the S-2001s will be good and you will not need new tubes.

Respond to these inquiries and I will give you some other things to try.

Anyone have a TS 820S VFO cable with both plugs wired of course to connect the TS820S to the VFO 820 ?
Sure would like to buy one..
thanks tim

6444. TS830S low power

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-17 12:41:32 UTC
From: vk5kyo
Topic: 6444 Message: 6444

Hi all

Having read all the positive comments in this group, I have decided that it is a must for any amateur to drive a Kenwood 830 if given the opportunity.
Well the opportunity has come but something under the bonnet is not well.
I have volunteered to repair an 830 of which the owner is complaining of
Low power on 1.8MHz,24MHz,28MHz, and No output on 18MHz,21MHz,29MHz
Other bands output claimed normal.
My own inital checks mostly agreed with the claims except that the bands with no power did in fact have some but very low.
So in short the following was done
1. Checked and cleaned band selector switches and alignment.
2. 12BY7 substitute.
3. 6146 substitute.
4. Aligned the TX slugs.
5. Bias set.
6. A good look around for the obvious.
The only thing I havent done yet is to neutralise it. For now adjustments are smooth and spectrum is clean.

I have managed to get full power on all bands now but still not on 18MHz and 21MHz. There is definetly something a miss there.

When I look at TP4 (grid of 12BY7) with a spectrum analyser, it all looks good and same level on all bands. That pretty well proves anything before that is OK.

This unit serial number is 103xxxx which I think is a fairly early one and that someone has enabled the WARC bands.

My question to the group is if you have any ideas of the cause.
I am sort of speculating maybe a common capacitor for those 2 bands.
I need to study the faded circuit a bit more.
But as beautiful as these rigs are, from a servicing point of view, not the easiest thing to replace components.
I'll appreciate your comments

Regards from Joan VK5KYO

Thanks Walt. Actually, it's Brian, kc2mrq
that is having these problems. My problem was that the 6146w's from Neb. arced and took out my cathode resistors. When I went back to the old original tubes, and replaced the CAthode resistors, the radio worked fine again. I tested the 6146W's in a tube tester, and they tested fine. Of course the tube tester doesn't apply 800 V to the plate. I have not had the courage to try the 6146W's again.

Hi Joan. I have just spent the last week or so removing the bandswitch from my TS-830, cleaning it thoroughly, applying a conductive substance across the rivet connections, and I re-assembled it yesterday. Previously I had no output on 15M, and it was intermittant on 12M. After I completed refurbishing the bandswitch contacts, I checked them with an ohmeter and they were very low resistance (about 0.05 ohm) and consistently made good contact. The results were that all intermittants are gone, but still no output on 15M. There is no ALC action with the Carrier control at maximum when tuning the Drive control through it's full range. All other bands have strong ALC indication at 9 to 10 o'clock on the Carrier control. I tried using my 100 MHz scope on TP4, but it loaded down the test point, so it is very interesting that you found the same drive signal strength at the 12BY7 on all bands and yet no output on 17M and 15M. My documentation is not with me right now, but I think there is a small capacitor across the 18 MHz coil, and there is no capacitor across the 21 MHz coil.

I am looking for suggestions just as you are, and would appreciate you letting me know what you find out. If I luck onto it first, I will certainly let you know.

You are certainly correct in that access to all the various components on the circuit boards is very labor intensive on the 830.

Good luck Joan.

Hi Ken.

The scope is a TEK 465B and the probe is a 3.5' TEK 6010 10X (10:1). I measured the probe center conductor resistance to be 9.06 Meg. ohms with a Fluke 8060A.

Since I had to go to my shop to get the probe info, I also picked up my data book on the 830 and brought it back to the house. Looking at TP4 on the schematic, I see that there is no RF choke in this test point. Maybe I should put an inductor in series with the scope probe for better isolation. Comments?

All other bands have strong ALC indication at 9 to 10 o'clock on the Carrier control. I tried using my 100 MHz scope on TP4, but it loaded down the test point, so it is very interesting that you found the same drive signal strength at the 12BY7 on all bands and yet no output on 17M and 15M. My documentation is not with me right now, but I think there is a small capacitor across the 18 MHz coil, and there is no capacitor across the 21 MHz coil.

6449. Re: [TS-520_820_530_830] TS830S low power

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-17 17:52:25 UTC
From: Bill Scurlock
Topic: 6444 Message: 6449

Ken,
Please dis-regard my comment about the RF choke/inductor in TP4. I must have had a "senior moment".

Bill, K5GCW

Subject: Re: [TS-520_820_530_830] TS830S low power

Hi Ken.

The scope is a TEK 465B and the probe is a 3.5' TEK 6010 10X (10:1). I measured the probe center conductor resistance to be 9.06 Meg. ohms with a Fluke 8060A.

Since I had to go to my shop to get the probe info, I also picked up my data book on the 830 and brought it back to the house. Looking at TP4 on the schematic, I see that there is no RF choke in this test point. Maybe I should put an inductor in series with the scope probe for better isolation. Comments?

Bill,

Were you using a 1:1 probe or a 10:1 (or 100:1) probe on your 'scope?

Ken, WA2LBI

On 1/17/06, Bill Scurlock <k5gcw@...> wrote:
> Hi Joan. I have just spent the last week or so removing the bandswitch from my TS-830, cleaning it thoroughly, applying a conductive substance across the rivet connections, and I re-assembled it yesterday. Previously I had no output on 15M, and it was intermittant on 12M. After I completed refurbishing the bandswitch contacts, I checked them with an ohmeter and they were very low resistance (about 0.05 ohm) and consistently made good contact. The results were that all intermittants are gone, but still no output on 15M. There is no ALC action with the Carrier control at maximum when tuning the Drive control through it's full range. All other bands have strong ALC indication at 9 to 10 o'clock on the Carrier control. I tried using my 100 MHz scope on TP4, but it loaded down the test point, so it is very interesting that you found the same drive signal strength at the 12BY7 on all bands and yet no output on 17M and 15M. OK, Bill, Have you checked the coils for the 15M band? An open/short
there would cause the problem.

6451. Re: [TS-520_820_530_830] TS830S low power

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-17 18:32:11 UTC
From: Bill Scurlock
Topic: 6444 Message: 6451

No Ken, I did not check the coil when I had the RF Board removed because I was concentrating on the Bandswitch being the problem. I will go look at the physical situation and see if I can get a test lead down to that position of the driver wafer switch. Otherwise, I'm looking at a couple of days labor removing and re-installing the RF Board, etc.

You said "coils" (plural). Since the receiver works on 15M, I think the only coil in question is L29 in the 12BY7 plate circuit. Am I wrong?

6452. Re: [TS-520_820_530_830] TS830S low power

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-17 19:08:51 UTC
From: Walt Breining
Topic: 6444 Message: 6452

I'd solder a 1 meg resistor to the test point keeping the leads short and look on the outside end of it. It should still give you a relative indication of level between bands. You might try this with the direct probe. While your probe shows close to 9 meg Dc it may have some reactance much lower than 9 meg.

> > Hi Joan. I have just spent the last week or so removing the bandswitch from my TS-830, cleaning it thoroughly, applying a conductive substance across the rivet connections, and I re-assembled it yesterday. Previously I had no output on 15M, and it was intermittant on 12M. After I completed refurbishing the bandswitch contacts, I checked them with an ohmeter and they were very low resistance (about 0.05 ohm) and consistently

made good contact. The results were that all intermittants are gone, but still no output on 15M. There is no ALC action with the Carrier control at maximum when tuning the Drive control through it's full range. All other bands have strong ALC indication at 9 to 10 o'clock on the Carrier control. I tried using my 100 MHz scope on TP4, but it loaded down the test point, so it is very interesting that you found the same drive signal strength at the 12BY7 on all bands and yet no output on 17M and 15M. My documentation is not with me right now, but I think there is a small capacitor across the 18 MHz coil, and there is no capacitor across the 21 MHz coil.

Bill,

I don't know if you are right or wrong. I wasn't scouring the roadmap
for specific details (I am at work and they, unreasonably!, expect me
to concentrate on my job, not my hobby) so I should have said coil(s)
in case there was more than one. Sorry that I possibly mislead you.

Ken, WA2LBI

concentrating on the Bandswitch being the problem. I will go look at the physical situation
and see if I can get a test lead down to that position of the driver wafer switch.
Otherwise, I'm looking at a couple of days labor removing and re-installing the RF Board,
etc.
>
> You said "coils" (plural). Since the receiver works on 15M, I think the only coil in
question is L29 in the 12BY7 plate circuit. Am I wrong?

6454. Re: [TS-520_820_530_830] TS830S low power

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-17 21:35:44 UTC
From: Bill Scurlock
Topic: 6444 Message: 6454

Ken,

You were correct. I got my lines mixed up on the schematic. There are input and output coils for the Driver stage. I just got confused because you tune the input coils as part of the receiver alignment, and the output coils are tuned in the TX mode. I was able to measure the resistance of each individual coil, so the 15M coils are not open. Although the sequence of resistance values makes sense (values are larger at the lower frequencies) and they change in a smooth progression (don't jump around) as you go from lower to higher frequency bands, I still don't know if that means the coils could not be partially shorted out. The coil resistance values in the input grid circuit vary from 0.09 ohm at 10M to 1.00 ohm at 75M, and in the output plate circuit they vary from 0.04 ohm at 10M to 0.49 ohm at 75M. These were measured with a Fluke 8060A, and test lead resistance was subtracted from the readings.

Now that I realize that the driver grid has been tuned as part of the receiver alignment, I think I will try tuning the 15M RF Amp coil in the driver grid during the TX alignment and see if that changes things. But, it may be a while before I have time to do that.

Thanks for your time Ken. Your assistance is greatly appreciated.

73, Bill, K5GCW

6455. Re: [TS-520_820_530_830] TS830S low power

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-17 22:42:00 UTC
From: Bill Scurlock
Topic: 6444 Message: 6455

Hi Walt. Yes, you are correct about the reactance of the probe. The Kenwood data specifies a maximum probe capacitance of 3 pf, and my probe has about 10 pf. According to the manual on my probe, the reactance gets fairly low at the higher HF frequencies which will load down test points.

Thanks for responding Walt.

73, Bill, K5GCW

Subject: Re: [TS-520_820_530_830] TS830S low power

I'd solder a 1 meg resistor to the test point keeping the leads short and look on the outside end of it. It should still give you a relative indication of level between bands. You might try this with the direct probe. While your probe shows close to 9 meg Dc it may have some reactance much lower than 9 meg.

> The scope is a TEK 465B and the probe is a 3.5' TEK 6010 10X (10:1). I measured the probe center conductor resistance to be 9.06 Meg. ohms with a Fluke 8060A.
>
> Since I had to go to my shop to get the probe info, I also picked up my data book on the 830 and brought it back to the house. Looking at TP4 on the schematic, I see that there is no RF choke in this test point. Maybe I should put an inductor in series with the scope probe for better isolation. Comments?

> > Hi Joan. I have just spent the last week or so removing the bandswitch from my TS-830, cleaning it thoroughly, applying a conductive substance across the rivet connections, and I re-assembled it yesterday. Previously I had no output on 15M, and it was intermittant on 12M. After I completed refurbishing the bandswitch contacts, I checked them with an ohmeter and they were very low resistance (about 0.05 ohm) and consistently made good contact. The results were that all intermittants are gone, but still no output on 15M. There is no ALC action with the Carrier control at maximum when tuning the Drive control through it's full range. All other bands have strong ALC indication at 9 to 10 o'clock on the Carrier control. I tried using my 100 MHz scope on TP4, but it loaded down the test point, so it is very interesting that you found the same drive signal strength at the 12BY7 on all bands and yet no output on 17M and 15M. My documentation is not with me right now, but I think there is a small capacitor across the 18 MHz coil, and there is no capacitor across the 21 MHz coil.

Bill,

I don't know if you are right or wrong. I wasn't scouring the roadmap
for specific details (I am at work and they, unreasonably!, expect me
to concentrate on my job, not my hobby) so I should have said coil(s)
in case there was more than one. Sorry that I possibly mislead you.

Ken, WA2LBI

On 1/17/06, Bill Scurlock <k5gcw@...> wrote:
> No Ken, I did not check the coil when I had the RF Board removed because I was concentrating on the Bandswitch being the problem. I will go look at the physical situation and see if I can get a test lead down to that position of the driver wafer switch. Otherwise, I'm looking at a couple of days labor removing and re-installing the RF Board, etc.

6457. TS-820S With No Plate Current Reading

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-18 00:19:53 UTC
From: Stephen Davis
Topic: 6457 Message: 6457

Hello All,

What a great group of folks! I joined several months ago with the intention of posting right away, but got sidetracked. In the meantime I have greatly enjoyed reading all the posts and learning a little bit with each one. Now that I have some time to dedicate to my "problem rig", I thought I would solicit the help of the group.

Last summer, I decided to get back into Ham radio after being away from it for a while. I purchased a TS-820S from eBay and turns out it receives good, but doesn't transmit. I would like to try to troubleshoot and fix it, but I am a novice at this sort of stuff and need help. Someone in a eHam forum suggested this trying this group for assistance, so here I am!

So, the radio is a TS-820S. It receives fine, but when I try to tune it up (into a dummy load), the symptom I have is a 0 IP reading. I have tried adjusting the bias control in the back, but nothing changes. The SG switch is in the proper position and I have the plug in the external vfo socket in the back. If I switch the meter to the HF position, it reads about 850 volts. The tubes all light up and I have changed out the 12BY7A.

Any suggestions on what my next steps should be would be appreciated. I have a volt/ohm meter but that's about all I have in the way of test equipment. I also have a pair of 6146A's, but not sure if they are a replacement for the S2001A's. Looks like I need the 6146B's or 6146W's.

Thanks all for any help or advice you can give!

Steve
K7QHU

Hi Bill

Were travelling the same road Bill, so thanks for the company and good
to hear from you.
If I find the problem before you do, I am sure to share it.
I have used your particular CRO for many years in the repair shop mainly
for 140Mb stuff, so I wouldnt have thought of any loading issues at the
frequencies were looking at. From memory the probe is the matching probe
for up to 400 MHz, just dont push the ID button while taking a measurement.
After all were not looking to make a calibration adjustment using the
CRO but rather to check relevant levels.
If Kenwood suggested less than 3pF for a CRO probe, I think most of us
amateurs will be in trouble.
It doesnt stop us from having a go and in most cases we get by with the
tools we have in the shack
Bill, I am using an older 10MOhm Tek probe with 12pf (because it is
6ft long I guess) for my relevant measurements and I think that is good
enough. The levels were measured all the same. If anything they actually
increased a bit as frequency went up. DC check on the coils are OK too.
I've misplaced my coils for the GDO, so I cant check resonance for now.
We'll keep the group posted

Joan

6459. Re: SWR creeping up

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-18 09:51:11 UTC
From: VA7CAB
Topic: 6208 Message: 6459

Hi Folks,

It's purely an issue on 17M as I was running 75 watts RTTY (contest only S&P) on 20 M and 50 watts PSK on 40M with no problem.

Will check the antenna length on 17 and see if it's kicking up some sort of fuss!

Thanks again!

73 Chris

Steve:
I doubt if it is tubes if their filaments are lit. The 6146 A's will work, but I think the S-2001s are best. After you get this sorted out, I'd put the originals back in and give them a try. The Toshiba 12BY7's are best as long as they are still good.

Unplug the rig and discharge the high voltage.

Inspect the two 10 ohm resistors from the tube cathodes to ground. R2 and R3. They are on the PA board. Look to see if they appear damaged. You should get an ohm reading of 5 ohms or slightly less from pin 1 of either tube to ground. If they are bad, be sure to replace them with 1 watt resistors as original. These act as a fuse and open if the cathode current gets way high and prevents frying serious things like the plate choke.

Check the plate choke, the long choke that feeds high voltage to the tubes for continuity. On the bottom of the plate choke there is a capacitor to ground and another choke. Check this choke for continuity. These should both read close to 0 ohms.

Now turn the rig back on. Place the mode switch in CW.

Carefully check the voltage from the point on the PA board labeled SG. It should read around 200 +VDC in CW. Be very careful while doing this. Don't be real critical about this reading, we are looking for something completely dead.

Let us know what the results of these tests were.

I still think it is the balun. Probably the SWR is higher or the complex impedance is lower or 17 causing the balun to heat up. You may need a current balun.

6462. Tuning CW power out probs

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-18 10:21:57 UTC
From: Christiaan Jacobs
Topic: 6462 Message: 6462

Hello

I have a TS-820, AT-200, ext VFO (not used but attached), feeding a G5RV. All grounded well.

I tune the rig into a dummy load with no dramas. I then follow the manual of the AT-200 to get a decent 1:1 load or at least under 1.5:1 on the freq of choice.

If I leave the carier control centered as in initial tuneup I get full output 100+ watts on the AT-200 used as a watt meter. However the manual for the 820 says on page 20 4.13 n blah blah blah The plate current should be about 200 ma. When I switch the meter to IP and then ruduce the Car to 200 ma my output reading on the AT-200 shows about 40 to 50 watts out.

Is this right? I know the AT-200 manual states that the RF meter can be incorrect when the SWR is high. Is this such a scenario?

From: Walt Breining
Topic: 6462 Message: 6463

Be sure that you have the A-200 tuned for lowest SWR with the power reduced at least at first. Be sure the drive is peaked for max with the meter in the rig set to ALC. Then adjust the plate and tune for maximum watts. Turn the carrier control fully up and readjust for maximum watts. As long as you are not exceeding 250 Ma. you are fine. If you are running CW, reduce the carrier so the meter in the ALC position runs about mid scale.

Check neutralization.
Tune up into the dummy load on 21.3 MHz first on tune. Peak the Drive for maximum with meter on ALC. Then peak the plate and the load until you reach maximum. Now go to CW with the carrier control full up and do the same thing. Do not stay keyed for more than 15 seconds at a time. Once this is done place the meter switch to IP. Watch the IP current and the watt meter as you slowly move the plate control through the watt peak or the IP dip. The optimum situation is for the IP to dip at exactly the same point as the watts peak and for the drop in watts to be about the same on either side of the IP dip. It doesn't have to be perfect, but close. If this is very far off, you need to touch up the neutralization. This will only be the case on 21.3 or close to it.

Walt:

I normally reduce my ALC until it reads zero. I still get a full 100 watts out right at zero and backing down a little more will drop the power. I think I found this in the 830 manual and I have noticed my sig looks cleaner on the SM-220 with ALC at zero.

Kevin:
Actually you are correct. I found that in the manual after reading your posts.
So Chris, please note this change.
I think what is happening is that he is not getting the SWR nulled out exactly with the tuner.
Thanks. Walt N9WB

6466. 853 members strong... wow!

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-18 13:57:51 UTC
From: Bill
Topic: 6466 Message: 6466

I would like to welcome all the new members that have joined our group lately; sorry I have not been able to acknowledge each one, but your "messages to group owner" on the application page are much appreciated and sure make the moderator's job a lot easier!

At any rate, welcome to the group; as you can see it's pretty busy and there is lots of info in the archives. More messages than you can or would want to search, most likely. So the "search" field comes in handy; try searching 6146B in the archives, and you will find a gold mine of info on the tubes in these rigs.

You may wonder why we chose to group the TS-520, -530, -820 and -830 into one group. Well, from a technician's standpoint, these rigs are quite similar in many ways; there are also a lot of differences. And, since many of our members own more than one rig and usually own several of different models of this genre, why not just have one group so we can address all of them? So far, it's worked out well. Many of the good ideas presented for one rig will work on most or all of the other models as well (shaft couplers, tubes, filter caps all come to mind, as well as tuning techniques, filters, etc).

Don't forget to check out the other club features, such as FILES and LINKS. I think we also have a database or two that need to be "fed" with info!

I would like to thank all our members for making this one of the very best groups on Yahoo; I can't count all the hams that have gotten help here and gotten their rigs back on the air. We are also a "DX" group in that many of our members are outside of the US and Canada. This is what I was hoping for, since ham radio crosses international boundaries, so should this group! All are welcome here.

Very 73 and God bless you all for a happy and healthy year,

Bill K0ZL

I'm not sure about the manual (don't have an 830 right now,) but the
original QST review of the 830 mentions that the ALC should be at zero on
CW for the cleanest signal. That is how I have run all my rigs on CW. I
cannot see any reason to want ALC action on CW.

From: Stephen Davis
Topic: 6457 Message: 6468

HI Walt,

Thanks for the suggestions. I have not yet tried the 6146A's in radio. The S-2001's are still in the rig. Here are the results of the tests you suggested:

1. The measurement across the 10 ohm resistors read 4.8 ohms, so they seem okay.
2. The measurement across the chokes basically show zero ohms, so I think they are okay, but not confident I did the measurement correctly. I measured from the top of the chokes to ground.
3. The measurement at the SG point on the PA board reads 268 volts when setting the mode switch to CW.

Thanks for your help and any additional suggestions you can give me.

73

Steve

Subject: Re: [TS-520_820_530_830] TS-820S With No Plate Current Reading

Steve:
I doubt if it is tubes if their filaments are lit. The 6146 A's will work, but I think the S-2001s are best. After you get this sorted out, I'd put the originals back in and give them a try. The Toshiba 12BY7's are best as long as they are still good.

Unplug the rig and discharge the high voltage.

Inspect the two 10 ohm resistors from the tube cathodes to ground. R2 and R3. They are on the PA board. Look to see if they appear damaged. You should get an ohm reading of 5 ohms or slightly less from pin 1 of either tube to ground. If they are bad, be sure to replace them with 1 watt resistors as original. These act as a fuse and open if the cathode current gets way high and prevents frying serious things like the plate choke.

Check the plate choke, the long choke that feeds high voltage to the tubes for continuity. On the bottom of the plate choke there is a capacitor to ground and another choke. Check this choke for continuity. These should both read close to 0 ohms.

Now turn the rig back on. Place the mode switch in CW.

Carefully check the voltage from the point on the PA board labeled SG. It should read around 200 +VDC in CW. Be very careful while doing this. Don't be real critical about this reading, we are looking for something completely dead.

Let us know what the results of these tests were.

Walt,

Yes I'm running SSB. I have set the idle current to 60ma, and peaked the plate. Still blowing fuses. What can I do? Neutralize?

thanks

6470. Re: Tuning CW power out probs

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-18 19:24:43 UTC
From: Christiaan Jacobs
Topic: 6462 Message: 6470

Hi Walt and others

Hmm I've been tuning with full power as I've followed the instructions step by step and that little bit of info is not included in the manual. My tuner doesn't seem to tune as good as it first did. I was attributing that to my poor antenna location. However could I have smoked the tuner? Could I have damaged the finals? I can tune to 1:1 if I change frequency and play around a bit but I can't just choose a freq and get 1 to 1 all the time. I have played with the tuner and a MFJ -259 antenna analyzer to see what and where I can get to 1:1 SWR.

Thank you

Chris VK2ICJ

6471. Re: [TS-520_820_530_830] TS-820S With No Plate Current Reading

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-18 22:22:34 UTC
From: Walt Breining
Topic: 6457 Message: 6471

After discharging the high voltage, remove the plate caps from the tubes and measure ohms from the top of the Plate choke to the bottom of it. Then measure from the bottom of the plate choke where the other choke joins it to the other end of this choke. They should show 0 ohms, a short through both chokes.

But I see a serious problem with the reading that you read inadvertently to ground. I suspect that your ohm meter was reading in reverse through the diodes in the HV unit. But this should be checked out. You should not read anything close to a short 0 ohms from the top of the plate choke to chassis ground. You should double check this. The reading should be several hundred thousand ohms.

Before beginning any of the above, unplug the rig and after it has sat for about 10 minutes, short the point labeled 800 on the rectifier unit, not the HV unit to ground. Leave it shorted for about 5 minutes and then REMOVE the short. Now check for a short between the top of the plate choke and ground. Place the black lead of your ohm meter to the top of the plate choke and the red wire to ground. Yes I meant red to ground. See what you read. It may show a short for 15 to 30 seconds and slowly increase to a high resistance over 47k as the capacitors charge. OR it may show a high resistance to begin with. Now do the same thing with the leads reversed. You may show a low resistance in this position even after 30 seconds. If you read a short in only one direction, you are reading this short through the HV rectifiers and this would be OK. If you are getting a short or low resistance both directions, we need to look farther.

Assuming that this checks out OK, do you have a means of measuring 800 v safely? How high does the DC scale on your meter go? Unless you are very familiar with the dangers of doing this, do not try it until you answer these questions and I can give you a procedure. We may want to make a simple voltage divider to do this.

BTW, we are saying that you cannot get any idle current and looking for this fault only. Just for the record, place the SG switch in the off position and with the rig on, Key it on CW with the carrier control fully up and the multimeter on the rig to ALC. Turn the drive control. Do you get an indication on the ALC meter? the 12BY7 will have to be installed for this. The finals can be in or out.

Don't forget to place the SG switch in the on position after you are done.

Let me know what you find.

I'll comment further, but if the rig tunes up to 100 watts on 20 meters and below and at least 85 watts on 10 meters, INTO A DUMMY LOAD, no tuner, then the finals are not the problem. You may want to try putting the dummy load on the tuner output and see if you can get a 1:1 that way with the tuner turned on. his would be a good test for the tuner.

I would take a shot and put another/the old finals back in
and try it. Don't remember if thats been tried. Eyeball the tube
cage for arcing or bad connections (power off, discharged etc.)
good luck

6475. RE: [TS-520_820_530_830] TS-820S With No Plate Current Reading

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-19 00:49:52 UTC
From: Stephen Davis
Topic: 6457 Message: 6475

Hi Walt,

Following your latest instructions, here are the results:

1. Both plate chokes show 0 ohms when measured as you described.

2. Putting black lead to top of choke and red lead to ground, it shows a low resistance to start with, then builds to a high resistance (about 400k).

3 Putting the red lead to the top of the choke and the black lead to ground, it shows a resistance of about 400k. (somehow I must of goofed up my original measurement).

4. I hooked up the dummy load, heater switch on, set the SG switch to off, meter to ALC, carrier fully clockwise. Toggled rec/send switch to send and held down the cw key while adjusting the drive control through-out its range. No movement of the meter.

5. My voltmeter has a 1000 VDC plug position for the red lead and on the selector switch there is a 250/1000 vdc position. I would be extremely cautious making any high voltage measurements.

Thanks again for your help. It would really be neat if we can actually solve this problem!

73

Steve K7QHU

Subject: Re: [TS-520_820_530_830] TS-820S With No Plate Current Reading

After discharging the high voltage, remove the plate caps from the tubes and measure ohms from the top of the Plate choke to the bottom of it. Then measure from the bottom of the plate choke where the other choke joins it to the other end of this choke. They should show 0 ohms, a short through both chokes.

But I see a serious problem with the reading that you read inadvertently to ground. I suspect that your ohm meter was reading in reverse through the diodes in the HV unit. But this should be checked out. You should not read anything close to a short 0 ohms from the top of the plate choke to chassis ground. You should double check this. The reading should be several hundred

thousand ohms.

Before beginning any of the above, unplug the rig and after it has sat for about 10 minutes, short the point labeled 800 on the rectifier unit, not the HV unit to ground. Leave it shorted for about 5 minutes and then REMOVE the short. Now check for a short between the top of the plate choke and ground. Place the black lead of your ohm meter to the top of the plate choke and the red wire to ground. Yes I meant red to ground. See what you read. It may show a short for 15 to 30 seconds and slowly increase to a high resistance over 47k as the capacitors charge. OR it may show a high resistance to begin with. Now do the same thing with the leads reversed. You may show a low resistance in this position even after 30 seconds. If you read a short in only one direction, you are reading this short through the HV rectifiers and this would be OK. If you are getting a short or low resistance both directions, we need to look farther.

Assuming that this checks out OK, do you have a means of measuring 800 v safely? How high does the DC scale on your meter go? Unless you are very familiar with the dangers of doing this, do not try it until you answer these questions and I can give you a procedure. We may want to make a simple voltage divider to do this.

BTW, we are saying that you cannot get any idle current and looking for this fault only. Just for the record, place the SG switch in the off position and with the rig on, Key it on CW with the carrier control fully up and the multimeter on the rig to ALC. Turn the drive control. Do you get an indication on the ALC meter? the 12BY7 will have to be installed for this. The finals can be in or out.

Don't forget to place the SG switch in the on position after you are done.

Let me know what you find.

Vy 73, Walt N9WB

From: Alan Wolke
Topic: 6477 Message: 6478

It allows you to use the band-scope feature of the SM-220. This function is basically a mini spectrum analyzer that graphically shows you where activity is on the band. Its basically the same thing as the spectrum scope built into rigs like the IC-756PRO.

There are two pan-adaptor models available. The BS-5 is for the TS-520/530 rigs (3.395MHz IF), and the BS-8 is for the TS-820/830 (8.830MHz IF) series rigs. Many other later Kenwood rigs use the 8.83MHz IF and have the required wideband output that can be used with this combination. The TS-870S is an example that can be used with the SM-220/BS-8 combo.

Hi Walt

Using 21.3 as suggested above the Setup was this.

Rig grounded and tuned to 21.3mhz
Rig coax to the AT200 input (AT200 also grounded)
Dummy load connected to Ant2

Tuned up with the tuner in the "through" position no dramas.
When I turned the Car down to 250ma via the IP meter I was between 90 and 100 closer to 100 watts. When I reduced the carrier to 200ma I was at 50watts

I then switched the AT-200 to "ANT2 tuned". I was able to adjust SWR to nothing on the meter just fine with the AT-200.

I didn't do any other testing as I'm about to fall asleep hihi.

I do not think that you have bad tubes.
I think that your watt meter may be reading low.
You may try some other watt meters. A Bird 43 or a Drake W4 are usually fairly accurate. the Bird is usually the standard if you can borrow one.
Everything seems to be OK except possibly the antenna. It may have values outside the range of your tuner on some frequencies. Sometimes you have to play with the tuner a bit to get the exact null point.
If you told me, I forgot. What kind of antenna are you using?

I blew several fuses on my TS820 until I got in there and replaced the weak cathode resistors. A guess, FWIW... But easy to check the values to see if they are still solid. Worth a check anyway.

6482. TS820 CW XMIT offset adjustment

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-19 14:53:08 UTC
From: compdsgnr
Topic: 6482 Message: 6482

Hello all. I'm new here, but not new to these great rigs. This group is a great source of info.

I recently inherited my Dad's 820S. I've noticed the RCV to XMIT offset in CW mode has drifted up to ~1080 Hz. This should nominally be ~800Hz.

I know on the TS830 there is an adjustment on the VFO module (L4) for setting this.

I haven't been able to locate a service manual for the 820. I assume there is a similar adjustment on the 820 VFO.

Can anyone with a manual help me locate the adjustment ?

Also, is there an electronic version of the 820 service manual available online ?

Tnx

Tom / N1BSQ

That would indicate that you are not getting drive. And if I understand correctly you are also not getting any idle current. You do not need drive to get idle current.

Let's double check this. Mode on USB or LSB, all tubes installed, SG on mike gain down, Filament switch on, Meter in IP. Key rig with send switch and watch the IP meter as you change the Bias control in the back. At one extreme the tubes should draw a lot of current. At the other extreme the tubes will draw little or no current. Do you get a reading on the meter in any bias position. If you do it should be set for 60 MA.

If you do not get a reading, do you notice a lot of heat coming from the final area with the bias control at one extreme or the other? If the bias was working but the meter was not, the tubes would get very hot while in transmit with the bias control at one extreme but not the other. If they do get very hot, unkey so you do not damage the tubes.

Now, check again that all tubes filaments are lighted including the 12BY7. Check this out in a dark room. Be careful and don't fumble into the high voltage!

If you get no idle current, no excess heat that changes with the bias control, and all tubes are lighted, next try removing the relays and inspecting the contacts. Look for burned contacts. Clean them. Remove only 1 relay at a time, as they are not the same although they look alike.

Now I may be making a fool of myself suggesting the relays, but in the limited time I had this afternoon, and with the very poor diagram I have, it seemed that the power source for the bias goes through Q5 on the RF board and comes to Q5 through a relay. I did not have the time to check this out thoroughly at this time, but it might be worth checking the relays. We are looking for a contact that is not conducting on transmit. Be careful when removing the covers on these relays, they are not available any more.

Tell us what you find out and I will try to get a better diagram. I have one on hard copy, but it is not here.

BTW, the rig should operate with the CW key unpluged.

Topic: 6457 Message: 6484

Hi Walt,

You are correct, I am not getting any idle current. All tube filaments are lit. I tried rotating the bias control in the back and keying the send switch as suggested. I did not notice excessive heating at either end of the rotation.

I have removed the relay housing (Omron type MH4P) from the relay board, but having trouble getting the plastic cover off. I am being very gentle so as not to break it, but not haveing much success. Will continue to try. In the meantime, just eyeballing the contacts, the contacts that are in the open position look very clean. I was looking a the schematic (a somewhat fuzzy copy) to try and determine what voltage is used across the coil to open/close the relay, but I could not tell. I was thinking this could be a way to test to make sure at least the relay(s) are opening and closing. If I can determine the voltage, is this a legitimate test? I also measured the resistance across the coil and it was around 380 ohms, which is the resistance stamped on it, so at least I know the coil is not open or shorted.

I will keep trying to get the plastic case off so I can actually clean the contacts. Just wanted to update you on my progress.

Thanks

Steve
K7QHU

Tom,

If you have a manual, take a look at Fig. 19 CAR UNIT. Locate in the CAR-1 UNIT, VR1, and in the CAR-2 UNIT, T1. I managed to adjust the CW offset by fiddling with these two components. Make sure you mark the position of each, and keep track of how much adjustment you make, just incase you need to put it back to where you found it. Bill or Walt may know of a more productive way of making this adjustment without fouling up something? There is a service manual available on-line. <ftp://bama.sbc.edu/downloads/kenwood/ts820s/> Good luck, and have fun. -jay, kb9wwq

Thank you Alan. That gave me some good info and sounds like a piece of equipment I would eventually like to add (if I can find one reasonable). Now - what is the difference between the VFO-230 and the 240. I found lots of listings and pictures for the 230, but virtually nothing for the 240. Thanks - Bill

Bill,

Try these links for pictures and brief info on the VFO-240 and VFO-230:
http://www.universal-radio.com/catalog/hamhf/vfo240.html
http://www.universal-radio.com/catalog/hamhf/vfo230.html

The main differences are that the VFO-240 has only an analog dial and
no memories, both features of the VFO-230.

Walt,

Another useful way of checking whether the PA heaters are being powered is to see whether the meter light dims slightly when the heater switch is turned from off to on. An advantage of this method is that you can do this with the covers on.

I deduced that the PA heaters of my TS-530S were not receiving power by this means. The problem was a poor joint on one of the tube bases - these joints get considerable temperature cycling and so may be prone to fracture.

Thanks Jay !

I did locate a service manual on mods.dk.
The manual specifies the adjustment procedure on CAR1 and CAR2 for this. Looks simple enough. I'll try it tonight.

Also looks like I need to align the coil pack. Very low drive on 28Mhz. Tubes should be good. Hope this does it.

Tnx

no memories, both features of the VFO-230.

I "think" (someone correct me if I am wrong) that the 240 is an analog VFO
that tunes by variable capacitor. The 230 is a PLL oscillator that varies
frequency by an encoder.

I had a 240, but I never had a 230.

Hello all in the group,

Paul you are correct,the vfo240 is an analog vfo and
the vfo230 a digital vfo with 20hz steps.
But the best thing is there is a mod, that changes the
dial per 360 degrees from 25kHz to 6.3kHz so
you could use the vfo230 for excellent cw tuning.
By the way the vfo 120 is the same as the vfo240, but
has the cabinet which matches with the TS120/130.
So there is only a different outfit but the same thing inside.
The vfo 230 should be the first choice if possible, the
second choice should be a not so wellknown DFC-230,
also 20Hz steps but made for mobile and is able to be used with a MC60
because you could do up/down steps with your microphone.Then last but not
least a vfo240 or vfo120 is good for split work.

Thanks Kay,
I forgot about the DFC-230. I had one with my TS-830S, in addition to the
VFO-240. That was a fun station to play with!

Hello to all, I'm a new member and owner of a TS520s rig. A friend of mine and I are having a debate about the proper tuning of the drive. In the manual it states to "peak the ALC reading (maximum meter deflection) with the drive control". My question is...do you peak the adjustment to the top of the ALC portion of the meter,(which is at approx 1 oclock), or do you make the adjustment for the full meter deflection outside of the ALC portion of the meter? approx 2 oclock or +40db. I hope this isn't a question that has been asked here many times before, if so, I 'm sorry.
Thanks for your input. I look forward to learning more about this rig by using this group.

Bought a TS-520 yesterday and have used tube gear in many moons.
It does load with no problem but not according to the manual. On my
manual Table 3. shows a Summery of Transmitter Tuning Procedures
which is a four step procedure. The first three steps are fine but
on the four step while Mode Switch is in CW position, Meter Switch RF
position Stand-by Switch Send and final procedure says "Peak RF
output by alternately adjusting the Plate and Load Controls. When I
put the switch to Send absolutely nothing on the rig meter or my
Autek meter.
I had the Carrier Control on number 5 position. Have a key connected
and when I depress the key can peak the Load and Plate Controls with
no problem and loads beautiful. This is on all bands. The Heater
Switch is on as well as in Vox Position. Know I have to be
overlooking something very simple but just can't see it. The rig is
very stable as power doesn't fluctuate no matter how long the CW QSO
is. The receiver is as sensitive as my Icom 746 and actually could
even be better!

Any ideas or suggestions would certainly be welcomed.

Thanks.
Wayne, NM3B

6499. TS-820S Low RX Sensitivity (I Killed It!)

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-22 04:37:15 UTC
From: Dave Franklin
Topic: 6499 Message: 6499

I have two parallel antennas that are close together. Today I loaded up on one while the 820 was powered up on the other. When I went back to the 820 the receive was way down. The sensitivity is down about 50dB.

Is there any protection in the 820S for receive overload? I was hoping that there was something to protect the RF amp but I do not see anything on the schematic that looks like a fuse etc.

I have a copy of the service manual and a signal generator. Plan to check further tomorrow.

Any help or advise would br greatly appreciated.

Thanks,
Dave Franklin

Yep, that was it! Right after I posted the message it dawned on me.
Knew it had to be something very simple as well as it loads. I work
95% CW so will keep the key plugged in and load it the way I have
been. Something that simple certainly makes me feel like

a "knucklehead"!

Sure appreciate your prompt reply.

Topic: 6493 Message: 6501

Peak the Drive for maximum with the meter in the ALC position.
While speaking on sideband, do not let the ALC reading peak above the ALC portion of the meter on voice peaks. This is adjusted with the mike gain control.

When operating CW, adjust the carrier control to the point that the ALC meter does not move or barely moves.

To tune up:

Preset
Place mode in tune position.
Place carrier control fully up.
Place load control to 12:00.
Place tune control in the range for the band selected.
Place multimeter on rig to ALC

Key rig and peak Drive for maximum or full scale ALC. Meter may peg on ALC when in tune.
Set rig multimeter for RF or use an external watt meter so you do not have to change rig multimeter.
Key rig and peak tune for maximum RF or Watts reading.
Un-key

Change to CW.
Key rig and peak Drive for maximum peak on ALC meter.
Peak Load for maximum RF or Watt reading
Then peak tune for maximum RF or Watt reading.
Peak alternatively between tune and load until maximum is achieved and then touch up drive for maximum ALC reading.

Do not stay keyed for more than 15 seconds at a time. If you need more time, un-key and let finals cool for 30 seconds, re-key and continue. As you get accustomed to this, you should be able to do the final peaking in the CW mode in 15 seconds or less.

It will be easier if you have an external watt meter. The rig multimeter can then remain in the ALC position and the external watt meter can be used to adjust the tune and load. If an external watt meter is not available, switch the multimeter to RF when peaking Plate and Load and back to ALC to peak Drive.

Again, while speaking on sideband, do not let the ALC reading peak above the ALC portion of the meter on voice peaks. This is adjusted with the mike gain control.

When operating CW, adjust the carrier control to the point that the ALC meter does not move or barely moves.

Hope this helps,
vy 73, Walt N9WB

Peak the Drive for maximum with the meter in the ALC position.
While speaking on sideband, do not let the ALC reading peak above the ALC portion of the meter on voice peaks. This is adjusted with the mike gain control.

When operating CW, adjust the carrier control to the point that the ALC meter does not move or barely moves.

To tune up:

Preset
Place mode in tune position.
Place carrier control fully up.
Place load control to 12:00.
Place tune control in the range for the band selected.
Place multimeter on rig to ALC

Key rig and peak Drive for maximum or full scale ALC. Meter may peg on ALC when in tune.
Set rig multimeter for RF or use an external watt meter so you do not have to change rig multimeter.
Key rig and peak tune for maximum RF or Watts reading.
Un-key

Change to CW.
Key rig and peak Drive for maximum peak on ALC meter.
Peak Load for maximum RF or Watt reading
Then peak tune for maximum RF or Watt reading.
Peak alternatively between tune and load until maximum is achieved and then touch up drive for maximum ALC reading.

Do not stay keyed for more than 15 seconds at a time. If you need more time, un-key and let finals cool for 30 seconds, re-key and continue. As you get accustomed to this, you should be able to do the final peaking in the CW mode in 15 seconds or less.

It will be easier if you have an external watt meter. The rig multimeter can then remain in the ALC position and the external watt meter can be used to adjust the tune and load. If an external watt meter is not available, switch the multimeter to RF when peaking Plate and Load and back to ALC to

peak Drive.

Again, while speaking on sideband, do not let the ALC reading peak above the ALC portion of the meter on voice peaks. This is adjusted with the mike gain control.

When operating CW, adjust the carrier control to the point that the ALC meter does not move or barely moves.

Hope this helps,
vy 73, Walt N9WB

>

Interesting.
On my 530 I get no reading in the RF position and was told when I bought it [four years ago !] that this was due to a blown diode, which I did once locate on the Circuit but never bothered to replace - preferring to use the external RF /SWR Meter as an indicator of output. One day I might do something about the low output on 15 [about 75 watts] and 10 [maybe 55] which I have always assumed to be the bottles going 'soft'.

The 520 which sits here gathering dust does [or did when last warmed up] at least give 100 watts plus on all bands - one day I'll find out how to take the screening cover off the Main C and do something about the 'crackles' - probably dirt - which occur at 200khz 'plus'. What makes you think it was only really used on 40 here in the UK. <smiles>
Anyway I've had it now since December 1997 and only had the lid off once to have a 'look'.

What makes you think that my motto is 'if it ain't broke......'

73 to All

Graham

6508. TS 520 Tune Up

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-23 00:27:49 UTC
From: wa3syr
Topic: 6508 Message: 6508

I don't have a manual for my 520 can some one list the proper tuning for
the 520 in the order it is done.

6509. SM-220 w/BS-8 for Trade (maybe sale)

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-23 03:24:08 UTC
From: Kevin der Kinderen
Topic: 6509 Message: 6509

First let me tell you the quick story. I just picked up another SM-220 on Ebay which appears to be in very good condition. So I'd like to get my current 220 to someone that can use it. Here's the situation.

The SM-200 I have for trade is in fair condition cosmetically and electrically. There are signs of rust on the outside case and a few screws missing. The slug in the can transformer (T-201 I think?) is broken off and can't be adjusted. I failed to find a replacement part for the transformer. There are no cables. The manual is a photo copy and you could probably find a better one on the net. There is a scuff on the top right front plastic.

Now for the good news. It functions well. The pan adapter (BS-8) works in spite of the broken slug. The cables are a no-brainer. The view of the transmitted signal looks good. Using V.Input for the second IF looks good. I have not tried the two-tone test nor have I used the unit with a linear. Inside, the unit looks clean. All the knobs and buttons function properly. The lettering is clean and bright. The trace is crisp and bright.

I'd prefer a trade rather than a sale but will go that route if I can't find anything. Here's a few things (in no particular order) that I'm hunting for to give an idea...

Original manuals for the 830S and accessories
VFO-230 to TS-830S cable
KB-1 knob
Extension feet
Anything else that might be of interest to a dedicated TS-830S, CW, digital operator

Suggestions?

Also, I'm considering trading my Ten Tec Delta II. I would be interested in a second TS-830S in excellent condition.

73,
Kevin - K4VD

6513. RE: [TS-520_820_530_830] TS520S Tuning proceedure

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-23 16:22:45 UTC
From: Hauser, Ron M.
Topic: 6493 Message: 6513

Hi Mike. Running the mike gain up so that the ALC peaks above the "ALC" mark on the meter while transmitting SSB will just make your audio sound distorted. If you have a way to listen to yourself with headphones while transmitting (into a dummy load preferably), you can really hear this. I don't know if the 520 has it, but on the 820 and 830, there is a monitor switch that lets you listen to yourself. If you can do this, you will quickly recognize the crunchy, squawking noise that comes from overdriving the finals. And then you will be able to recognize other people's bad audio too <grin>. Very educational.

I believe that in CW when you run with any ALC action at all, you tend to get clicks on the beginning or end of the elements. In any case, your cleanest, most readable CW signal is with no ALC action at all.

Hope this helps

73

Peak the Drive for maximum with the meter in the ALC position.
While speaking on sideband, do not let the ALC reading peak above the
ALC
portion of the meter on voice peaks. This is adjusted with the mike
gain
control.

When operating CW, adjust the carrier control to the point that the
ALC
meter does not move or barely moves.

To tune up:

Preset
Place mode in tune position.
Place carrier control fully up.
Place load control to 12:00.
Place tune control in the range for the band selected.
Place multimeter on rig to ALC

Key rig and peak Drive for maximum or full scale ALC. Meter may peg on ALC
when in tune.
Set rig multimeter for RF or use an external watt meter so you do not have
to change rig multimeter.
Key rig and peak tune for maximum RF or Watts reading.
Un-key

Change to CW.
Key rig and peak Drive for maximum peak on ALC meter.
Peak Load for maximum RF or Watt reading
Then peak tune for maximum RF or Watt reading.
Peak alternatively between tune and load until maximum is achieved and then
touch up drive for maximum ALC reading.

Do not stay keyed for more than 15 seconds at a time. If you need more
time, un-key and let finals cool for 30 seconds, re-key and continue. As
you get accustomed to this, you should be able to do the final peaking in
the CW mode in 15 seconds or less.

It will be easier if you have an external watt meter. The rig multimeter
can then remain in the ALC position and the external watt meter can be used
to adjust the tune and load. If an external watt meter is not available,
switch the multimeter to RF when peaking Plate and Load and back to ALC to
peak Drive.

Again, while speaking on sideband, do not let the ALC reading peak above the
ALC portion of the meter on voice peaks. This is adjusted with the mike gain
control.

When operating CW, adjust the carrier control to the point that the ALC
meter does not move or barely moves.

Hope this helps,
vy 73, Walt N9WB

I assume that you mean on SSB. The transmitted audio will have an over compressed distorted sound and background room noise will "pump" up when you pause speaking.

Now please note that often the ALC meter pegs when peaking the drive on tune. When you retune the drive on CW, It will not be full scale so you can find the exact peak with the drive control. When operating CW, the CW waveform will be best if the carrier control is reduced after tune up to the point where there is little ALC. This gives a better CW waveform. On SSB the ALC should not pass the top of the ALC scale very often. When I use external processing, I set the ALC to peak at 10 dB or less depending on how "tight" my processing is. The 520 processor is better than the 820 processor. When using the processor in the 520, reduce the ALC a bit more than full scale for best audio.

From: Walt Breining
Topic: 6506 Message: 6515

I assume that you are placing the mode in CW. You will not get any reading in SSB. (You probably knew that.)

I use an external watt meter and just leave the multimeter in ALC. I peak the drive in CW for max ALC, and alternately adjusting the Plate and Load Controls for max on the watt meter.

6518. Getting active after 10 years!

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-24 03:29:38 UTC
From: wb4ouf
Topic: 6518 Message: 6518

Hi everyone.
I "dug" my old 820S and VFO 820 out a few weeks ago and have been going through it "fixing" the little bugs that it has developed after so many years in storage. At first, I thought I would have to get a new rig but, after cleaning contacts, controls and connectors and re-soldering a couple of opens in the vfo cable, it has settled down fairly well. Probably should get it aligned but, have no idea by who and for how much $. Anyway, wish me luck and, hopefully will get it back on the air as soon as I get an antenna up. Right now I just have some wire hooked up (just for listening). Am looking forward to working some cw again and have been surprised that I am still able to copy about 20wpm after all these years. May be asking some questions as this project unfolds so am glad I found this group. Also, may be looking for an AT200. I don't have a lot of room for a full scale antenna farm anymore. So if you know of one, please drop me a line.... Thanks es 73s....
Frank.

6519. Re: [TS-520_820_530_830] Tuning the 520

Yahoo group: TS-520_820_530_830 (2006)

From: catboat15@aol.com
Topic: 6519 Message: 6519

This is according to the manual as I have not had a lot of practice yet.
1. Put the meter in IP. Check to see that the idle current is 60 ma. with the stand by switch in SEND.
2. Turn meter to ALC Mode to TUN and use the DRIVE to peak
3. Meter in IP and still in TUN dip plate current with PLATE control
4. Meter in RF and Mode in CW peak the RF using both Plate and Load controls.

This is all assuming you are tuned to the band and close to the freq you want to operate.
You can operate at reduced power using the CAR control when on CW mode or by the MIC control when on SSB.

If you are new to the 520 I would practice this with the set cold, then in receive to find the dials and controls as you should not hang around with full output and not tuned properly.

6520. Kenwood TS-520 CW

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-24 06:27:28 UTC
From: wayneg
Topic: 6520 Message: 6520

Hello again with another question.
I work all CW and getting the loading procedure down right,
hopefully. According to the manual on CW the meter should be within
the ALC area. Was running out of the ALC area at about 65-70 watts.
Went through the loading steps again and with the meter switch in RF
position and keydown with "needle" on the 210 ma mark my Autek meter
shows just about 50 watts output. This was on the 40 meter band. I am
assuming the meter switch should be on the RF mark? When I switch to
ALC on the meter with key down there is no movement on the meter which
I also assume is correct?

So, anything over 210 ma on CW would be slowly "zapping" the finals?
Seems like there should be better explanations in the manual for CW
operating or maybe I'm overlooking something?

Thanks again.
Wayne, NM3B

Welcome back Frank!!!!

You sound fairly handy with the soldering iron so why not make yourself a resonant dipole for 40 meters which will give you some on 15 as well. Cheap and easy while you look for an AT-200. Ebay seems to have heaps of them from time to time.

Hi Wayne

I'm seeing essentially the same thing and as you I am confused. I posted earlier and got this result.

http://groups.yahoo.com/group/TS-520_820_530_830/message/6463

From what I can tell up to 250ma is acceptable from this message.

Wayne

6524. CWTYPE software interface

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-24 22:47:16 UTC
From: Ken McGowan
Topic: 6524 Message: 6524

I have a ts-830, and i'm trying to make a interface to work with CWTYPE.

The interface ins't working, because (or at least I think), the
voltage at the key is 65vdc.

Has anyone tried this?

And, if yes what did you do to get it to work?

Any help would be great.

Thanks & 73,

w1nyg

You need a keyer/interface for grid block keying. I purchased one off
the Internet but I'm sure it could be easily built.

hi,

To help me with the tuning, I just remember
Drive Plate Load

From right to left on the top of the rig,
the controls are drive, plate and load.

The manuals for the ts-520 and other models
are available at no cost to download at
HamFtp.

Here is a link, you need to join up like you
did for this forum.

usen an opto-isolator to keep the 65v away from your computer.

1k resistor from PC keying line in series to pin 1.
1n914 or eq diode across pin 1 & 2.
Pin 4 is gnd to key jack on rig.
Pin 5 is hot on key jack on rig.

Bill:

Do you know anything about it's history? Was it in operation last week
or has it been in storage for 15 years? You might need to take
different approaches to the first start up depending on the answer.

For tests, I'd just try following the tuning procedures for each band
into a dummy load and record some of the settings including power out,
meter readings and approximate positions of the LOAD, PLATE, DRIVE
settings. It might make a nice reference if you need to troubleshoot
problems further down the road.

Congrats on the 830! Wonderful rig.

I do have a TS-830S as well and I built my own interface, it works perfect with both serial and parallel ports. You need to use a PNP transistor with a BVCBO high enough to handle the -65VDC from the rig, I think I used a 2N5401 from the junkbox and a PN2222 to drive it, I can send you the diagram tonight when I get home if you want.

6539. "Scratchy " receive

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-26 00:56:52 UTC
From: Grant McDuling
Topic: 6539 Message: 6539

Hi Guys,

I am experiencing 'scratchy' receive especially on CW. By this I mean, if I tune across the CW portion of the 40m band, the signals don't strengthen up as the dial sweeps across the transmitting frequency, they are very broken up and scratchy until I stop the dial on the frequency; then it sounds normal. Is there something that needs attention in the receive circuit? Has anyone come across something like this before. It's a little difficult to explain, but I hope you get the idea.

Grant VK4JAZ

6540. CWTYPE software interface

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-26 03:32:02 UTC
From: pjcoombs@frontiernet.net
Topic: 6524 Message: 6540

Ken,

I'm guessing that the 830 uses -65 VDC on the key line, just like the 820. If so, then you can just build the two transistor interface almost as shown in the help file. Instead of the 2N2222 (NPN), use a PNP that can handle the 65 volts for the "KEY-IN (+)" section - or, add the pnp into the circuit as it exists and you can use the same controller for a positive key line as well. I used an old TV vertical output transistor along with the parallel port (D-25) circuit in the help file. All you need to do is switch the transistor leads around a bit. Hook the pnp Emitter to where the npn Base goes. The pnp Base gets grounded. And the pnp Collector goes to the KEY-IN (now -). Connect a protection diode from the pnp collector, + side to ground. It would also be a good idea to put protection diodes on the inputs, + side to the key-in Emitter, and + side to the PTT Base (npn). Works great, even though I only use a SPDT reed switch for the paddle.

From: catboat15@aol.com
Topic: 6541 Message: 6541

In a message dated 1/25/2006 8:22:01 PM Pacific Standard Time,
TS-520_820_530_830@yahoogroups.com writes:
I have the Kenwood TS-520, 25 ft of ladder line, and wire for dipole.
My question is: does it matter if the wire is run North-South or East-West
or NW-SE?

What is required since I do not have an antenna tuner?
Bill: Every antenna has a pattern where the signal is strongest. In a dipole
in free space the most signal is at right angles to the wire. If there is no
trees buildings etc in the way and depending on how high you can get the wire
the right angle to the antenna is pretty true.
I assume you will feed the antenna with coax since that is what the TS-520
has for the output connection. Cut the length of the antenna in accordance with
formula for the frequency you want to work. The pi filter on the output does a
pretty good job of matching if you are close to the correct length. (the LOAD
control adjusts the antenna match if in a reasonable range)
Generally an inverted V antenna is closer to the 50 ohms the transmitter
likes to work into.
What I would recomend is to save your pennies and try to get some kind of
tuner with a meter or meters so you are not working by guess work. Too long a
period when things are badly mis-matched can cost you a pair of output tubes in a
short time. After all the radio will put out power and if it can not go into
the antenna and into the air the power is spent in the transmitter and can
cause problems.
Sometimes a tuner (particuarly the older ones) are called "Transmatch" and
there are circuits in the Amateur handbook for some designs you can home brew
yourself.
The best thing you can do is to find a club or an Elmer nearby who can help
you get on the air.

Ken,

Take a look at N0XAS' Universal Keying Adapter 2...it's a $15 kit. I
don't own one but I do have his PicoKeyer kit, which works great.

Grant:
You didn't say which rig it was. I often see this in rigs that have been sitting for a while. Often this will get better with use. The problem is the connections between the rotor plates of the tuning capacitor and the frame of it. Carefully remove the cover over the VFO capacitor. On the rear of the capacitor is a spring type thing that connects the rotor plates to the frame of the capacitor. Clean this very well with De Oxit. The scratches will go away. I bet you have a 520 because the readout would be intermittent with the scratches if it were an 820.

1. It does not make any difference which way you run the wires.
2. You need an antenna tuner that will accept balanced line or an antenna tuner and a balun.

6546. One more mic question

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-27 02:53:43 UTC
From: Bill
Topic: 6546 Message: 6546

I have my new (to me) TS830 on its way. In an effort to be prepared to check it out when it arrives, I needed to round up a mic for that radio. I have been given a Kenwood mic that came off of a dead TR 7730 (2 mtr FM mobile). It is a 6 pin (up/down buttons), 500 ohm, dynamic mic. I have a spare 4 pin plug and the schematic to wire it up.

So, is anyone familiar with this mic and should it be adequate until I can get an mc-50 or an equivalent? Any warnings to pass along while I prep the mic plug? Thanks - Bill

6547. BS5 mod to BS8 for SM220 ???

Dear All

Before I go mad, ripping rig apart, does anyone know cure for following scenario?

Rig fuse blew (don't know how - hadn't used for ages), got new fuse, "Power On" now good but no LCD frequency read-out.

By the way, when I first powered the rig back up, I am sure that the LCD display was there briefly, but faded to nothing.

Regards
Rob, G4LMW

hi rob,

Since the radio was not used in a long time,
best to check all ground screws at the
pc boards, sometimes there are poor
connections and the radio will not work properly.

Topic: 6546 Message: 6552

Well, I started wiring the 4 pin for the mic mentioned below and ran into some trouble. It turns out there are only five conductors (not six). One of N9WB's prior postings, along with Kwd's mic wiring diagram plainly describe the 4-pin requirements. The #4 position requires a wire from the mic ground My problem is identifying the remaining wire for that #4 position. On the 6-pin diagram - nothing is identified with that function.

The there is a black wire coming off of the mic element that is soldered to the bare ground wire, along with one coming from the up/down switch and the ptt switch. Should I detach that wire and attach it to one from the (now useless) up/down switches to provide that path/position? Or am I really messing this thing up? Does this make any sense?

Thanks,

Bill

I personally do not recommend this. Some very knowledgeable people who I have a great respect for do however. A 25% increase is about a 1 dB increase. You are reducing the life of the tubes, increasing the stress on the transformer and HV rectifier board. One of the good things about hybrid rigs that use 6146 tubes is that they are far more forgiving than those that use 6JS6 tubes. This will reduce this cushion, so to speak. And all for a 1 dB increase? Remember an S unit is 6 dB so this increase is 1/6 of an S unit. Although I have never measured this, I expect that this radio "Hot Rodding" will reduce linearity and increase IMD products. Remember that the components in these rigs are not getting any younger.

Using better coax, better connectors, tuning the antenna more closely, or installing the antenna better or installing a better antenna is a better way to get at least 1 dB improvement. Also many can benefit from a better sounding mike or some quality speech processing.

Or, if you really need more soup, get an amplifier.

My 820 is my "pet" radio. I would not do that to it.

Just my opinion.

Like Walt, I wouldn't recommend it either. Had an 830 several years ago
that I got on a trade that had the QRO kit in it. Ran it side by side
with my own 830 that didn't have the QRO kit. Same mike and same antenna,
the receiver at the other end could not hear or see any difference in
signal strength. Sold the 830 with the QRO kit several months later to a
guy about 20 miles from me. Less than a year later, he was on a search
for a replacement power transformer for that 830. Want a better signal;
put up a better antenna or get yourself a linear.

The Shield wire goes to pin 4. The wire surrounded by the shield goes to pin 1. Remove the wire that goes to the shield from the switch, and replace it with one of the now unused up/down wires. At the plug end connect the other end of this former up/down wire to pin 3 on the mike plug to provide a separate ground for the switch going to pin 3. Now this wire will be connected to a wire coming from pin 2 when the switch is depressed.

The shield ground will be pin 4. The switch ground will be grounded at pin 3.

These actually go to two different ground points inside of the radio. Sometimes you can use pin 4 for both audio and switch ground, but often this causes RF problems due to a ground loop.

If this is confusing, please tell me the color of the wires and where they go in the mike.

What you get is some parts, mostly resistors and the knowlege about how to do this. There may be a diode and some small caps, I can't remember. What it does is raises the screen voltage and makes some changes in the ALC to accomodate this change. If this is what you want to do, the kit is worth the money and the modification works well. And I will admit the increased stress it puts on the rig is small. But as I said before, It slightly increases the stress on the rig, it only gains 1 dB or 1/6 of an S unit and I don't want to increase the stress on my rig even slightly, for an increase that will never be noticed on the air.

If you really want to make an 820 sound stronger, and you use the processor, get the TOG mod for the TS-820 speech processor. It will make the processor brighter and louder. I personally do not like it because I am an audio purist and I don't care for the 820 processor. I use external processing of my own. I tried the TOG processor mod in an earlier 820 and it did make the processor better. I didn't bother to put it in my "pet" 820 because I am building an external processor that meets my personal criteria much better.

Topic: 6559 Message: 6559

My MC-50 'toilet roll' mod (thanks Walt) on my TS-820S made all the difference by increasing top
and middle. If I remove it during a QSO, I'm asked to put it back.

If close-talking the mike is causing increased bass, try a little distance and compensate by mic
gain to maintain proper ALC. If not, a small series cap will decrease bass.

Slide a toilet paper tube over the slots on the side. If you carefully cut it to about the length of the slots, you can slide it up to cover all of the slots or back to slightly expose them for the correct tone balance.

I gave Ira pretty much the same advice off reflector.

The ironic thing is that I met Ira for the first time on the air the night before his post and his TS-830 sounds great.

Leave it alone.

Want more boost then make a better antenna and get an amplifier.

I never knew what rig he had. If it is an 830 and not an 820 his processor
is superior as is. I would not touch that either. Except for the bandswitch
issues, the 830 is one of the best rigs ever made. Walt N9WB

Thanks to all for your responses. Mostly, I was curious what was going on effect the increase as claimed by Inrad, which Walt answered.

I'm very happy with the TS830. I came back into ham radio last summer, after a 30 year hiatus, and I was considering everything from an Apache/HQ170 (my K3PAK rig in 1962) to an IC718 or 706 for my first 'get back into the hobby' rig, and the '830 fit the niche. I got a good deal on Ebay, and I've been surprised how well this gets out to work some nice DX with my stealth wire. Matter of fact, I picked up another 830 I'm restoring as a backup (broken bandswitch coupling).

Thanks again to all!

Toilet roll can be eliminated by using a heat gun to soften the assembly adhesive of the mic grill and using "construction paper" insert a rolled tube inside the mic grill. Then reassemble using a small amount of clear silicone rubber.

Some people like the toilet paper roll on the mic!! So what ever "turns you on"....

Thanks Walt for your help ...

Yup, I am a little confused. On this mic (remember it is a 500 ohm/Knwd dynamic mic from an old TR7730)there are 5 conductors. There is no "shield" but there is a bare/non-insulated wire. The original pin-out is as described in the Knwd Misc Connectors TSB. Or = Pin 1 has a white wire for "microphone" and it does come from one side of the mic element. Pin 2 has a heavy black wire and it comes from one side of the switch. Then pin 3 has a blue wire which goes to the "down" switch. Pin 4 has a red wire, going to the up switch. Pin 5 is vacant. Pin 6, in the middle, has the bare wire and is labled chassis ground. This wire has three black mic wires attached - one from the switch, one from the mic element and one from the up/down circuit board.

Now, here is where my confusion lies (or at least some of it), you noted that pin 4 should have the shield. I assuming this can be equated with the bare wire (from the original pin 6). But, the same Kenwood Service letter (and my pdf copy of the TS830 manual) shows pin 3 = "Chassis Ground" or PTT ground. Then, pin 4 shows to be the mic ground. Or does it really matter and I am making this harder than it really is?

Actually, this is kinda fun and is why I am getting an 830 in the first place - in order to learn/re-learn much of what I have forgotten. Just wait till I get open up and get inside that box!

73,
Bill

Found this on a Kenwood Mod site on the web. Thought it might be of interest.

Steve W4IMF

I would like to pass on the problem I have encountered in connection with the QRO modification to the Kenwood radios TS830S, TS-530S and the TS-530SP.

The problem occurs after many hours of long winded QSO's. It seems that with the increase in the screen voltage from 210 to 300 volts, R37 on the RF unit (#X44-1360-00) heats up tremendously and will change it's value so greatly that even the receive either suffers or goes out totally. R37 originally is Metalfilm resistor at 3.3K ohms and is 1/2 watt.

I have changed mine to a Metalfilm as original same value but have used a one watt resistor. The brand I was able to get was RCA and I suppose there are better on the market. This is a 2% tolerance. Three units that I know of have had this problem that I took care of in this area alone. Two units were TS-830S and one a TS-530SP. Just thought I would pass that information along for what it is worth. (Thanks, Frank J. Lukas, Jr., 5301 Main Ave., North Ridgeville, OH 44039)

6567. TS-820 20M only display dramas Help

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-28 22:41:17 UTC
From: vk2icj
Topic: 6567 Message: 6567

Hello

I'm seeing some odd digital display when using 20 meters only. The other bands do not seem to have this drama.

When tuning the VFo knob between 14.00 and 14.1 MHZ the 10khz digits add an extra line here and there. The 2 looks like a backward 6 , the 5 is a 9, and the 6 is an 8 IE if the
display is supposed to be 14.050 I'm seeing 14.090. If you keep adjusting the freq upwards between 14.1 and 14.11 I see the exact same numbers acting up but now they have moved one decimal place to the right, and the 10khz position is fine. IE if I should be
seeing 14.105 I see 14.109. If I keep tuning upwards I get the same 3 numbers with dramas but again one more decimal to the right. IE 14.110.5 on the display reads 14.110.9

Any thoughts?

thanks in advance
73

Chris VK2ICJ

6569. RE: [TS-520_820_530_830] TS-820S With No Plate Current Reading

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-29 02:33:56 UTC
From: Stephen Davis
Topic: 6457 Message: 6569

Hello All,

Update on my problem with my TS-820S radio. Still no transmit on the radio. The symptom remains the same, that is unable to get any bias reading when trying to tune the rig (if I switch meter to hf position I do get a reading of about 850v). Thanks to Walt, these are the things tried so far in troubleshooting the radio:

Checked the cathode resistors (ok).
Checked Plate chokes for short (ok)
Checked relay on relay board (ok, or I should say contacts are clean and relay moves when I switch from rec to send)
Checked SG switch (ok)
Filaments light in all three tubes.
Substituted all three tubes, no change in symptoms.

Any thoughts on the next steps I should take to troubleshoot this would be appreciated. I really would like to get this rig on the air!

Thanks

Steve - K7QHU

Subject: RE: [TS-520_820_530_830] TS-820S With No Plate Current Reading

Hi Walt,

You are correct, I am not getting any idle current. All tube filaments are lit. I tried rotating the bias control in the back and keying the send switch as suggested. I did not notice excessive heating at either end of the rotation.

I have removed the relay housing (Omron type MH4P) from the relay board, but having trouble getting the plastic cover off. I am being very gentle so as not to break it, but not haveing much success. Will continue to try. In the meantime, just eyeballing the contacts, the contacts that are in the open position look very clean. I was looking a the schematic (a somewhat fuzzy copy) to try and determine what voltage is used across the coil to open/close the relay, but I could not tell. I was thinking this could be a way to test to make sure at least the relay(s) are opening and closing. If I can determine the voltage, is this a legitimate test? I also measured the resistance across the coil and it was around 380 ohms, which is

the resistance stamped on it, so at least I know the coil is not open or shorted.

I will keep trying to get the plastic case off so I can actually clean the contacts. Just wanted to update you on my progress.

Thanks

Steve
K7QHU

To: TS-520_820_530_830@yahoogroups.com
Subject: Re: [TS-520_820_530_830] TS-820S With No Plate Current Reading

That would indicate that you are not getting drive. And if I understand correctly you are also not getting any idle current. You do not need drive to get idle current.

Let's double check this. Mode on USB or LSB, all tubes installed, SG on mike gain down, Filament switch on, Meter in IP. Key rig with send switch and watch the IP meter as you change the Bias control in the back. At one extreme the tubes should draw a lot of current. At the other extreme the tubes will draw little or no current. Do you get a reading on the meter in any bias position. If you do it should be set for 60 MA.

If you do not get a reading, do you notice a lot of heat coming from the final area with the bias control at one extreme or the other? If the bias was working but the meter was not, the tubes would get very hot while in transmit with the bias control at one extreme but not the other. If they do get very hot, unkey so you do not damage the tubes.

Now, check again that all tubes filaments are lighted including the 12BY7. Check this out in a dark room. Be careful and don't fumble into the high voltage!

If you get no idle current, no excess heat that changes with the bias control, and all tubes are lighted, next try removing the relays and inspecting the contacts. Look for burned contacts. Clean them. Remove only 1 relay at a time, as they are not the same although they look alike.

Now I may be making a fool of myself suggesting the relays, but in the limited time I had this afternoon, and with the very poor diagram I have, it seemed that the power source for the bias goes through Q5 on the RF board and comes to Q5 through a relay. I did not have the time to check this out thoroughly at this time, but it might be worth checking the relays. We are looking for a contact that is not conducting on transmit. Be careful when removing the covers on these relays, they are not available any more.

Tell us what you find out and I will try to get a better diagram. I have one on hard copy, but it is not here.

BTW, the rig should operate with the CW key unpluged.

Vy 73, Walt N9WB

If you look at the reviews on eham for the AT-250 there is a ham using this tuner with the 830. There is mention of a special cable needed to interface the rig. Which one and how to use it I don't know.

What sort of antenna do you plan on using? The 830 itself will tune a lot of antennas.

Some of the fun in owning these rigs is all the adjustments that need to be made to operate them. Using a auto tuner takes away some of the fun if you ask me. An AT-200 or AT-230 will give you some more knobs and switches to play with. The 200 does not have the WARC bands. If it was me I'd get a AT-230 or another manual tuner for your rig.

Cheers Mate

Topic: 6457 Message: 6571

I am assuming the following. If I an wrong, please tell me.

With the rig keyed in SSB, mike gain down, meter in the IP position, no matter where you adjust the bias pot on the back of the rig you get no IP reading?

Assuming the above, with the rig keyed and set as above, Measure the voltage to ground on the terminal on each end of the Bias pot. Then place the meter on the center terminal and see if the voltage changes as you rotate this control. Give me readings with this full CCW, fully CW and center.

Unless you read 0 voltage on the center of the Bias pot in all positions, go to Radio Shack and get 3-100 K ohm resistors at 1 watt.Let me know when you have done this.

Vy 73, Walt.

6572. RE: [TS-520_820_530_830] TS-820S With No Plate Current Reading

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-29 18:51:52 UTC
From: Stephen Davis
Topic: 6457 Message: 6572

Hi Walt,

Your first paragraph is correct.

I took the following measurements at the bias pot.

Bias pot fully counterclockwise: left terminal -95v center terminal -105v right terminal -105v
Bias pot centered: left terminal -95v center terminal -95v right terminal -105v
Bias pot fully clockwise left terminal -95v center terminal -95v right terminal -105v

I took measurments with mode set to lsb, band set to 40 meters, mike gain down and with the send receive switch in the send position. All other controls set per the table in the manual for initial transmit tuning.

I am on the way to Radio Shack to pick up the resistors.

Thanks

Steve

6573. TS-820S AF/RF Gain Control Replacement

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-30 00:51:36 UTC
From: wb4ouf
Topic: 6573 Message: 6573

Hi All!
Anyone have any idea where I might be able to get the dual pot, AF/RF Gain Control for my 820S? The part number is R08-3012-15 and it's designated VR4.5 in the manual. I have searched East Coast Transistor and the folks on the West Coast.... both show "discontinued". Also, no luck on the "Web". If anyone knows anything about this part, I could use one. Thank you, es best 73's to all.

Frank.

6574. Re: [TS-520_820_530_830] TS-820S AF/RF Gain Control Replacement

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-30 09:20:27 UTC

Is the original scratchy / damaged / missing?
If scratchy, Deoxit can be used to fix it..

6575. TS-830S AF board relay replacement

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-01-30 09:28:17 UTC
From: mw1fgq
Topic: 6575 Message: 6575

Hi
I'm trying to restore a junker TS-830 which someone has "worked" on previously, it looks as if the Omron flatpack 4PCO relay on the AF board needs replacing - the cover was missing and I have no IF shift/RIT even after trying to clean it. Is there a current replacement part that I can easily source here in the UK? I've looked through the messages/files but can't find anything relevant.

This old set came to me as a source of parts for my own 830 and had obviously been neglected, I'm thinking of making her into a transverter driver for higher bands - has anyone done a solid state driver mod for this or would that be sacrilege?
Apart from the carrier oscillators being way off I can hear the VFO/VCO working so I'm hopeful that the relay will help solve my Rx problem but I have no frequency display - are there any likely stock faults to look for?
Many thanks, great group
John

Thanks for the reply Dave. The AF gain is scratchy. I had this rig in storage for about 10 years and have it working pretty good except for the AF control. I have used spray contact cleaner (not Deoxit) and, have cleaned it several times but the problem just won't go away. It will be working just fine and suddenly, the AF starts acting up. A slight turn of the control and, it settles down. I just figured, if I could get the part I could "end this grief"..... HI!

6580. TS-830 w/audio problem

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-02-02 04:19:38 UTC
From: Bill
Topic: 6580 Message: 6580

Well, my 830 arrived and the receive audio is scratchy and occasionally fades out. A little twist of the AF knob and the audio returns, only to fade out or become very scratchy again later. It does maintain proper sound if the AF is turned up to, say, 6 or 7. This problem does not appear at all when using headphones. Volume changes and audio sound perfect. Is this just a dirty pot that can be cleaned? Or is there something more sinister at hand?

Also, does anyone know of what or where to get some touch-up paint for the face plate? I have a few very small knicks.

Thanks,

Bill

6582. 'Fix' lamp comes on -- and other items

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-02-02 04:59:45 UTC
From: Bill Barron
Topic: 6582 Message: 6582

I'm working to get my TS-520SE operational. I've made good progress and can even get the rig tuned up and resonating into a dummy load -- even though the max RF I'm getting is about 55 watts -- probably a function of aged, soft 6146s. [IP and ALC are on spec].

I've got all the accessories -- the VFO-520S, the DG-5, the SP-520, the SM-220 and the tuner and can't wait to get the whole thing running smoothly.

Three questions:

1) I'm missing one plastic toggle arm over the wide/nar switch. Does anyone know where I can get a replacement?

2) My VFO-520S doesn't seem to want to work with the 520SE. Neither does the spare VFO-520 I have. Is this just a bad interconnect cable problem?

3) The 'fix' lamp illuminates on some [not all] occaisions when the function switch is placed in VFO mode. The lamp does not light ever in the VFO.R position. Is this just a quirk or bad / leaky switch, or is it a sign of more serious issues? I can't see that it effects the rig at all. The proper VFO jumpered plug is inserted in the rig. No fixed channels are installed.

73,
Bill W1WAB

Topic: 6580 Message: 6583

I would check the contacts on the headphone plug and speaker plug and any pugs associated with cables going to these plugs. The speaker audio goes through the headphone plug and is disabled by contacts in the headphone plug. I would use de-Oxit to clean these contacts. Spray it on and repeatedly plug and unplug a plug a few times working the de Oxit into the contacts.

Also clean the AF pot with De Oxit. Actually problems caused by dirty contacts often are affected by changes in gain.

If that doesn't do it, check for bad solder connections around the audio chip and associated components. I am betting on the contacts though.

Waly is right on the money here. De-Oxit is a friend to those that own older equipment.

A thorough cleaning of all controls and contacts will breath new life into these beasts that have been religated to the basement, attic or garage for a while.

You are dealing with componenets taht are over 30 years old and have been in many unknown environments. In some cases they have either had little or no maintenance and in others they have been allowed to just sit and tarnish.

When ever trouble shooting anything, go for the simplest solution first.

What is a good source(cheap) for De-Oxit?

A while back there was a wide ranging discussion on lubricants for older switches. Was any consensus reached?? While I do not have any switch issues with my 520S I want to keep it that way. The most feared failure, for me, is a multi-position rotary switch.

My understanding of this □situation□ is that towards the end of 830 production, Kenwood ran a sales promotion where they offered the 830 with all filter slots filled, so that there were no additional □internal□ accessories to buy. Whether or not they actually referred to these □promotional□ 830s as □gold□ or □gold-line□, or whether these monikers are the product of rumor & Ebay sales hype I don□t know. I do know that both 830s I□ve owned had gold colored labels under the main tuning dial. Both of them came to me through Ebay without optional filters, and every other 830 I□ve ever seen also had the gold colored label. 73□s, Calvin WOØL.

The Gold TS 830 uses special beta components that will outlast standard 830s and incorporates a electron accelerator in a the screen grid circuit that has several advantages. It was coveted by DX'ers because their signals would arrive at the DX station slightly ahead of the others giving a decided advantage in pile ups. Unfortunately, the ARRL threatened to pull all of Kenwood's advertising from QSTs if they did not cease manufacture immediately. They considered this cheating in the contests and DX operations. Kenwood complied and the Gold Kenwood was short lived. These rigs are rare because DX'ers who have them seldom sell them or let it be known that they own them for fear of government reprisal. when they do end up on e-bay it is rumored that the government runs the biding up and snatches them up never to be seen again.

Bob Heil later coined the name Gold Line for one of his microphone lines and it is rumored that he incorporated a speech accelerator diaphragm in some of his Gold Line elements, but Bob is very hush hush about this. I think that there may be some truth to this because hush hush is not one of Bob's typical characteristics.

6598. 830S No RX.....Help

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-02-03 06:36:10 UTC
From: Bill Marvin
Topic: 6598 Message: 6598

Hi Group,

I was touching up a few pots & switches with a light amount of DeOxit Pro Gold, all was working. Then when I plugged it back in No Rx, no Rx display. However when I flip the Send/Rx switch to Send the display work per VFO, in Rx Blank....even the Rx Rit light doesn't glow.

I treated the Send/RX switch, the Rit switch & Pot, AF & RF pots.

It does appear to Tx fine.......... Any hints

Good one Walt!

The Goldline was actually part of the 'Olympic series'; Gold, Silver and Bronze.
I couldn't understand the manual. It was all Greek to me.
Instead of dipping, it said to break the plate.

Cheers
Dave F4EYK

I got this tip from Carol on the Fox Tango site. If they don't have your exact color, Go to Wall Mart or a craft or hobby shop and get Testors craft and model paint in little bottles. Get one the color lighter and one the color darker than what you need. Poor some of the lighter color into a small container. mix the darker in a bit at a time until it becomes your color.

6603. Question about TS-830S vintage

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-02-03 18:33:43 UTC
From: Dylan Keon
Topic: 6603 Message: 6603

I've seen one 830S with a fixed power cord and another with a plug-in interface for the power cord and an adjacent voltage select switch. I'm curious - which is the earlier design, and which is later? I think the unit with the fixed power cord had a lower serial number, but can't remember for sure.

Thanks,
Dylan Keon KA8PFC/7

6604. Re: [TS-520_820_530_830] Question about TS-830S vintage

Dylan:

I bought one of the first 830's around 1982, and it had a power cord. As I recall, at that time that was the only option. Of course, I'm commenting based on my memory, which doesn't work as well as it did in the early 80's...

Be careful there is HV present use insulated tool only.. keep one had in your pocket at all times do not have both hands touch the rig......

Tune the rig to 10 meters the highest frequency.... anywhere on 10.....meters
Tune into a dummy load and a watt meter....
make sure the maximum output occurs at the dip on the plate meter...
When that occurs that is proper neutralization..

Wayne, look in the ARRL Handbook. Building an RF Probe is fairly simple. Then you can use any DC voltmeter (analog meters are easier than digital) with a 10 Megohm input on a low voltage scale to monitor the voltage across a 50 ohm dummy load - put a coax TEE at the output of the radio to access a measurement point. Follow the instructions in the radio manual, and be careful to avoid touching any wiring inside the radio while you do the adjustment.

You can use a separate receiver, but sometimes that will receive signals via more than one path, and can be confusing. But, properly connected and shielded, it does work. If you try this, be careful not to directly connect the external receiver to the transmitter you are neutralizing, and you will probably need some variable attenuation of some kind to obtain a low S-Meter signal to work with.

I'm leaving town. Maybe someone else can give you further assistance. Good luck.

6614. TS830s - No Power Out

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-02-04 22:17:06 UTC
From: Bill
Topic: 6614 Message: 6614

Well, I will try and post this one more time. This will be the third attempt.

After tuning up, my 830 no longer shows any power out. I am new to the 830 and I assume I have been tuning correctly. I have check the driver, using the suggestions posted in the files section, and it appears ok. This is a new rig to me, and my prior experience has been strictly with all-solid-state. But, that's why I got this rig in the first place.

Earlier, I was using Deoxit on some of the audio components. I also removed the driver tube for inspection and clean around the socket. All appeared to work properly, tuning up as before, but then no power out. If I leave the heater switch off for a while, it works again or will tune again. The plate current does seem to drift more now (40 to 70ma). Could I have caused this? What do I check now, keeping in mind I have very little hands-on experience at this point.

The rig is going to the doctor next week for a bandswitch coupler, and he could also diagnose this problem. But, I would like to know ahead, possibly fixing it myself or at least learn something. Any suggestions?

Thanks - Bill

One additional bit of info; I have had the radio about 5 days and
had a few QSOs. No signs of a problem. Also, no smell, arcing or
associated noise. I do not know how old the tubes are or how long
it was in storage (but it sure looks good!). What do I do next?

6618. 830S in Standby??

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-02-05 00:33:27 UTC
From: Bill Marvin
Topic: 6618 Message: 6618

Hi Group,

For some reason my near mint 830S seems to be in a No Rx Standby
mode. The display works by switching the Send switch but on Rec
no receive and the display is blank.

I used DeOxit lightly on all harness conectors, Send/Rx switch and
on the large & small bottom relays contacts,carefully.

When putting the 830 in Send I can see the large Bottom relay switching
but no activity on the small relay.

Any suggestions? It was working fine.

Best 73

Bill,

If you don't have a service manual I suggest you buy and/or download one. It will make troubleshooting much easier. With the manual in front of you the folks on the reflector can advise what and where to check and you can follow on the schematic. Also, you will see what SHOULD be happening that isn't. For example, you will see what should be causing that small relay to operate and trace backward to find why it doesn't.

Good luck,

Ken, WA2LBI

From: Rick May
Topic: 6603 Message: 6622

Hello,

The 830S with the fixed power cord through a grommet is the U.S. model. The 12 pin plug in version with the voltage switch was sold in either Europe or Asia depending on what voltage it selects between (220/240 Europe or 120/240 Asia although Japan uses 100 volt mains) Some models with the plug/switch had provision for 13.8vdc operation. I included a photo of the power connection of my 830S which has this option. There is no correlation between the serial numbers of the various versions.

Rick KC0HH
Lamar, Colorado

Dylan Keon <dbkeon@...> wrote: I've seen one 830S with a fixed power cord and another with a plug-in
interface for the power cord and an adjacent voltage select switch.
I'm curious - which is the earlier design, and which is later? I
think the unit with the fixed power cord had a lower serial number,
but can't remember for sure.

Thanks,
Dylan Keon KA8PFC/7

6623. TS-830 no pwr out

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-02-04 21:39:39 UTC
From: Bill
Topic: 6623 Message: 6623

Hopefully this post is not a dup. I posted it earlier today and it did not show up.

My recently arrived 830 now does not show any power out after tune up. I believe I have been following the proper tune-up procedures (I am new to hybrids, having only used all-solid state prior) and it appears to tune up initially. Then either immediately after tuning or after one or two transmissions, -no pwr at all. I followed the instructions (posted in the files) to check the driver and it appears ok. I guess next would be the 6146Bs. I am very limited on test equipment and with experience regarding this rig, but are there any other suggestions at this point. I have not witnessed any arcing, smoke or associated smell. I had made several contacts in previous days with no apparent problem.

If I turn the heater off for a while it will tune again, and again still later the power-out fails. Another change in characteristic is the plate current. Before, it was always at 50 to 60ma. Now it is fluctuating between 40 and 70ma.

Earlier, I was poking around inside the 830 today, cleaning some of the contacts with Deoxit (see my earlier post regarding the AF audio problem) and that appears to have been corrected. I also pulled out the driver tube to check its socket and clean around the base (the rig was off, of course). Could I have caused this?

I do not know the age of the tubes or how long this rig was stored, as it has just arrived a few days ago. It will be going to the rig doctor for the bandswitch coupler as it has a fracture but has not broken yet. And he can always diagnose the remaining problem. But, I would like to know ahead, possibly fixing it myself. Or at least learn something in the process.

Any suggestions? Thanks and 73, Bill

U.S. model. The 12 pin plug in version with the voltage switch was
sold in either Europe or Asia depending on what voltage it selects
between (220/240 Europe or 120/240 Asia although Japan uses 100 volt
mains) Some models with the plug/switch had provision for 13.8vdc
operation. I included a photo of the power connection of my 830S
which has this option. There is no correlation between the serial
numbers of the various versions.

You need to order two plugs and then make up a cable. I used cat 5
shielded cable. Wiring is straight through.

From: Kelly Maiden
Topic: 6610 Message: 6628

Your welcome, and good luck on making your cable. I found that my VFO
820 worked better than the onboard VFO. Less noisy, better audio.
I think because the inboard tuner needs cleaning.

I saw all the answers so far, basically I had to do the same thing,
order the plugs, I don't know why Kenwood had to go with that odd
arrangement, and then used regular CAT5 wire. If I can use CAT5 for
LAN runs out to 300ft and the same with "P" type phone sets, it should
be good enough for a short jumper. Haven't noticed any problems, good
luck with it.

hi bill,

sorry you have not rec'd any replies,

one place to check is the cathode resistors,
four 20 ohm 1/2 watt values, r2,r3,r4 and r5

if they are out of spec this can cause your problem,
if you need to replace them please use the
same 1/2 watt rating as they protect other vital
parts of the radio.

another thing to check is
C69 150pf between Q6/Q7 and grid 1 input of 12BY7A

hi,

The operating manuals for these radios
have the pinouts for the vfo and transverter
connections on or about pages 14-20

Thanks James! I will give those suggestions a try. It was kind of odd. I had to post this question three times over a period of 24 hours before it showed up on the list. Yahoo must have thought I was Spam! I will be printing the service manual (at work - better printer) tomorrow. Any other suggestions, procedures, etc. (especially any cautions) would really be welcome. Thanks again - Bill

hi don,

pinout is in the owner manual, here is the data if
you don't have the manual

1 ground
2 not used
3 NC relay contact
4 ground
5 NO relay contact
6 ALC feedback
7 not used
8 external speaker

Is there a way of telling if an SM-220 has the bs-8 pan adapter
installed from only viewing the outside? Thanks - Bill

6637. Re: [TS-520_820_530_830] SM -220 Question

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-02-06 04:26:24 UTC
From: Alan Wolke
Topic: 6636 Message: 6637

Bill,

You can tell if it has a BS-8 or a BS-5, but you won't be able to tell the difference from the outside. To see if it has one of the two pan adaptors installed, take a peek through the three holes on the left side of the cabinet (the side closest to the CRT). There are three holes, towards the rear of the unit - two about halfway up, and one below. If you can see trimmer cap screw-heads in these holes, then a panadaptor is installed. If you just see inside the cabinet, there's no pan adaptor.

Alan

6638. Re: [TS-520_820_530_830] sp-230 vs sp-180

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-02-06 08:12:47 UTC
From: Richard Harris
Topic: 6605 Message: 6638

Bill,

I believe that they are the same, just a different type label. You can
download a schematic and specification from www.mods.dk that is common to
both types.

I guess it is just a bit of marketing by Kenwood, selling the same product
as the SP-230 for the 530/830 and the SP-180 for the TS-180.

Richard G3OTK

6639. Re: [TS-520_820_530_830] TS830S low power

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-02-05 15:48:10 UTC
From: Joan de vk5kyo
Topic: 6444 Message: 6639

Hi everybody

For those interested in my original posting of the message, read below.

I am assuming that no other person has seen this problem before, except Bill-K5GCW who got in contact with me and explained he has the same problem with his 830, even after spending some considerable time cleaning the wafer switches.
Well if you read this Bill, I have found the problem(s). If your lucky, it may be the same problem.

A recent posting by another Bill-WB5DX, who cleaned the switches with de-oxid?? and has gone backwards in the process, may also be interested in reading this, because I think Bill may have disturbed the rivet connections of the wafers, or maybe some cleaning material is lodged in the switch as it is difficult to get in there, or he may have even bend some of the contacts. Its not hard to do.

Anyway
I did as what most of you would do and that is to remove the RF board, number each wafer, desolder each one and clean the switches and while it's out, you also solder each wafer contact to the track of the switch. This requires a lot of patience and a bit of skill to reassemble and realign all the switches before soldering them back on the board.
I found a number of contacts which were loose. The rivets were not doing their job anymore. The material must have shrunk a little. This is why you have to solder them, if you want the 830 to be reliable.

Now in Australia I heard of a saying, that whenever something gets serviced (be it electronics or otherwise), they say that "it has gone in for a grease and oil change".
It's a funny expression but when I pulled apart this wafer switch, I could relate to that. 2 of the switches had a liberal coating of a thick, greasy substance, and the RF board had a coating of what appears to be oil. It was a big cleaning job.
But all the cleaning and soldering made absolutely no scrap of difference. Still very little output on 18MHz, and no ALC at all.
I lost track of the number of times I pulled that RF board out.
For those that havent worked on these, you can make only limited measurements because the way it's mounted, and access to the track side of the board while it is switched on is near impossible.
I knew where the problem area was, except everything appears to be checking out. eg component values, connections, switches etc etc.
Then I found a bypass capacitor C74 which measured 500 Ohms I replaced and with excitement put it together. I improved the output on 21 MHz considerably, but still not much happening on 18.

If you study the circuit, you will wonder how this capacitor could have an affect on the output. (It all makes sense later on)
Then tonight, I finally had a breakthrough. I have been so close for days but missed it.
The neighbouring component to C74 is a RF choke L36. This choke has gone nearly short. It measured 30uH with a large D factor. The original value is 470uH.
Needless to say, I was very excited to have found it long last. I put it all back together and aligned the RF board again and output on 18 MHz was finally achieved. Output on 21 MHz was also restored. All in all, a good outcome.
I have learned a lot from this repair. One of them is that the circuit from Kenwood has mistakes in it. One that led me on the wrong path for some time until I checked the circuit board against circuit.
You know, I could have sworn it was going to be a band switch problem from all the symptoms it gave and I would have never guessed the faulty components. When you check everything methodically and logically over and over and over again and it still dont work, you know your in a bit of trouble.
So in the end, finding the problem, was it a fluke, lucky maybe? I dont know. What I did learn, was to make no assumptions, lots of patience, be tenacious, dont doubt what you have learned in the past, how the circuit works and I can go on. I feel great about it and someone more experienced may have done it in a tenth of my time, but you can never put a price on what you learn. I am sure the owner of the rig will be very happy too-No charge.
I know the story is a bit long winded, but I hope that for some of you readers that may develop this fault later on in the rigs life, you will save some time repairing it and get it back on air asap.

6640. RE: [TS-520_820_530_830] sp-230 vs sp-180

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-02-06 14:42:03 UTC
From: Hauser, Ron M.
Topic: 6605 Message: 6640

A question about these speakers... I gather from reading the
descriptions that the speaker includes some AF filtering? Anyone care
to comment on what the filters are doing, are they just some high
pass/low pass filters in the speaker itself? It sounds like a good
idea, and I might either get one of the originals, or perhaps built
something.

Thanks for your thoughts!

Subject: Re: [TS-520_820_530_830] sp-230 vs sp-180

Bill,

I believe that they are the same, just a different type label. You can
download a schematic and specification from www.mods.dk that is common
to
both types.

I guess it is just a bit of marketing by Kenwood, selling the same
product
as the SP-230 for the 530/830 and the SP-180 for the TS-180.

6641. RE: [TS-520_820_530_830] sp-230 vs sp-180

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-02-06 16:45:12 UTC
From: Richard Harris
Topic: 6605 Message: 6641

Ron,

Looking at the specification and the schematic, there is a switch which selects a series capacitor and which rolls off the low frequency response (3dB point at 400Hz) and two switched inductors giving three combunations and which roll off the high frequency response (3dB points 1kHz, 1.5kHz or 3KHz). With none of the switches selected then the response is unfiltered.

6642. Re: [TS-520_820_530_830] TS830S low power

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-02-06 18:09:06 UTC
From: Bill Scurlock
Topic: 6444 Message: 6642

Hi Joan. That's great that you found the problem(s). I struggled for a week or so after our last email, and then decided that I wanted to enjoy the radio for a while. The only thing that doesn't work is 15M transmit, so I have been having fun with it on other bands for a week or so. I understand how L74 and C36 could "kill" the drive signal, but it looks like it would affect all bands - unless there is some weird series resonance going on that was close to 15M in my case. You can bet I will check those components the next time I take the radio apart. In all my troubleshooting processes, I made some photos and some resistance measurements that I would be glad to share with you. The photos show the repair process I used on the switch rivet problem. If you are interested, please send me your email address and I'll forward them to you as attachments. I think the size of the photo files are in the 250KB range, and the Excel spreadsheet is small. My email is k5gcw@... .

I also followed WB5DX's comments with interest. However, since I had carefully measured the resistance of each individual switch contact during repair and after being reassembled (several times), I did not think that was my situation.

On 15M, I can get about 3-5 watts output, and there is a very broad peak when tuning the Drive Control - so broad that tuning L29 makes almost no difference at all. The 15M signal at TP4 actually appears to be slightly stronger than on the other bands. Since the receiver works well on 15M, logic seems to tell me that the problem could only be in switch S1-7 or L29, but as you discovered, L74 and C36 are common to all bands. Obviously, if I was smart enough, I would have found the problem by now! So my logic is not that dependable!

Thanks for giving us the results of all your work Joan.

73, Bill, K5GCW

Subject: Re: [TS-520_820_530_830] TS830S low power

Hi everybody

For those interested in my original posting of the message, read below.

I am assuming that no other person has seen this problem before, except
Bill-K5GCW who got in contact with me and explained he has the same
problem with his 830, even after spending some considerable time
cleaning the wafer switches.
Well if you read this Bill, I have found the problem(s). If your lucky,
it may be the same problem.

A recent posting by another Bill-WB5DX, who cleaned the switches with
de-oxid?? and has gone backwards in the process, may also be interested
in reading this, because I think Bill may have disturbed the rivet

connections of the wafers, or maybe some cleaning material is lodged in the switch as it is difficult to get in there, or he may have even bend some of the contacts. Its not hard to do.

Anyway
I did as what most of you would do and that is to remove the RF board, number each wafer, desolder each one and clean the switches and while it's out, you also solder each wafer contact to the track of the switch. This requires a lot of patience and a bit of skill to reassemble and realign all the switches before soldering them back on the board.
I found a number of contacts which were loose. The rivets were not doing their job anymore. The material must have shrunk a little. This is why you have to solder them, if you want the 830 to be reliable.

Now in Australia I heard of a saying, that whenever something gets serviced (be it electronics or otherwise), they say that "it has gone in for a grease and oil change".
It's a funny expression but when I pulled apart this wafer switch, I could relate to that. 2 of the switches had a liberal coating of a thick, greasy substance, and the RF board had a coating of what appears to be oil. It was a big cleaning job.
But all the cleaning and soldering made absolutely no scrap of difference. Still very little output on 18MHz, and no ALC at all.
I lost track of the number of times I pulled that RF board out.
For those that havent worked on these, you can make only limited measurements because the way it's mounted, and access to the track side of the board while it is switched on is near impossible.
I knew where the problem area was, except everything appears to be checking out. eg component values, connections, switches etc etc.
Then I found a bypass capacitor C74 which measured 500 Ohms I replaced and with excitement put it together. I improved the output on 21 MHz considerably, but still not much happening on 18.
If you study the circuit, you will wonder how this capacitor could have an affect on the output. (It all makes sense later on)
Then tonight, I finally had a breakthrough. I have been so close for days but missed it.
The neighbouring component to C74 is a RF choke L36. This choke has gone nearly short. It measured 30uH with a large D factor. The original value is 470uH.
Needless to say, I was very excited to have found it long last. I put it all back together and aligned the RF board again and output on 18 MHz was finally achieved. Output on 21 MHz was also restored. All in all, a good outcome.
I have learned a lot from this repair. One of them is that the circuit from Kenwood has mistakes in it. One that led me on the wrong path for some time until I checked the circuit board against circuit.
You know, I could have sworn it was going to be a band switch problem from all the symptoms it gave and I would have never guessed the faulty components. When you check everything methodically and logically over and over and over again and it still dont work, you know your in a bit of trouble.

So in the end, finding the problem, was it a fluke, lucky maybe? I dont know. What I did learn, was to make no assumptions, lots of patience, be tenacious, dont doubt what you have learned in the past, how the circuit works and I can go on. I feel great about it and someone more experienced may have done it in a tenth of my time, but you can never put a price on what you learn. I am sure the owner of the rig will be very happy too-No charge.
I know the story is a bit long winded, but I hope that for some of you readers that may develop this fault later on in the rigs life, you will save some time repairing it and get it back on air asap.

Not sure if you got the source for the 9 pin "plugs". I got two from:
East Coast Transistor Parts, Inc.
2 Marlborough Road
PO Box 238
West Hempstead, New York 11552

They were $5.04 each + shipping...
Best Luck es 73's
Frank....

6644. TS 820S Freq. Display Problem

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-02-06 20:36:15 UTC
From: wb4ouf
Topic: 6644 Message: 6644

Well, I finally got some Deoxit and it worked GREAT on my audio control problem but.... now I have no display? I did clean all the connectors and switch contacts with the Deoxit and when I fired it up there were a lot of improvements. The audio was clearer, the receiver noise went from an S8 to nil, all switches operate smoother and the VFO works perfectly BUT the display it out completely. I went back and re-connected everything...no luck. I then went to my service manual and got as far as checking the 5V supply. It's OK and all connectors seem to be "making" just fine. Anyone have any suggestions?
Thanks es 73's
Frank...

6645. RES: [TS-520_820_530_830] Re: VFO Cable for 820

Ok Frank, thanks for information, there is no Original Cable for this VFO ? Plugs and the shielded cable? I need the two plugs and the shielded cable too .

73´s

Excume-me for my poor Inglish ok.

6646. RES: [TS-520_820_530_830] Re: VFO Cable for 820

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-02-06 21:42:10 UTC
From: wb4ouf
Topic: 6610 Message: 6646

That is correct. The cable assy. is no longer available. You can
order the two end plugs and, as one other has suggested, get a piece
of shielded CAT 5 cable (ethernet cable) and wire it up as per the
diagram in the manual. That should do it....
Good luck es 73's
Frank....

6647. RES: [TS-520_820_530_830] Re: VFO Cable for 820

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-02-06 21:47:24 UTC
From: PY2FWA
Topic: 6610 Message: 6647

OK Frank, i will make this....

73

Alvaro
PY2FWA

-----Mensagem original-----
De: TS-520_820_530_830@yahoogroups.com
[mailto:TS-520_820_530_830@yahoogroups.com] Em nome de wb4ouf
Enviada em: segunda-feira, 6 de fevereiro de 2006 19:42
Para: TS-520_820_530_830@yahoogroups.com
Assunto: RES: [TS-520_820_530_830] Re: VFO Cable for 820

That is correct. The cable assy. is no longer available. You can
order the two end plugs and, as one other has suggested, get a piece
of shielded CAT 5 cable (ethernet cable) and wire it up as per the
diagram in the manual. That should do it....
Good luck es 73's
Frank....

Regarding question #2. Most likely a bad cable, use your ohm meter to check for continuity through each wire. When you connect the VFO-520, does the DG-5 blank out and you seem to lose all receive noise? If so, then you definitely have a bad connection in the cable.

I'll let wiser heads attack the other two questions.

Frank,

These display problems are often caused by poor connections on the DG-1.
Take a look at this
link for a good procedure for eliminating the problem.

http://www.radiomods.co.nz/kenwood/kenwooddg1.html

73 and Good Luck,
Dave

With a magnifying glass, check the solder connections to the pins where the supply and the display cables plug into the box. They often break loose on the solder side of the board. I particularly suspect this since you had these unplugged and replugged.

Hi Frank

I agree with Walt.
I have worked on my TS930, 940, TR-7730, TR-9130 and the latest a
friends TS-830 and while unplugging the board, I even pulled whole
connectors out of circuit boards.
Kenwood must have had a big problem with their soldering process on a
large number of earlier sets. Many of these ailments have already been
posted and are well documented.
Other than finding a lot of dry joints, I also found the connectors pins
nickel plating or whatever they used tended to seperate from the pin
after many years of operation.
All the best finding it.

6655. RE: [TS-520_820_530_830] TS830S low power

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-02-07 18:12:35 UTC
From: Hauser, Ron M.
Topic: 6444 Message: 6655

Bill and Joan, thanks for posting all this information. My name is Ron and I have an 830 that I acquired which seems to have a similar symptom, in my case no drive and no power on 30m (receive ok). All other bands output ok, but some intermittent behavior that I am tentatively attributing to bandswitch problems. This rig had bad cathode resistors when I first got it so I made those repairs and have been just enjoying the rig for a while. But I am about ready to pull the covers off again and see if I can figure out the 30m problem. Bill I would appreciate if you would send your photos and other data to me at rhauser@...

Thanks!

Subject: Re: [TS-520_820_530_830] TS830S low power

Hi Joan. That's great that you found the problem(s). I struggled for a week or so after our last email, and then decided that I wanted to enjoy the radio for a while. The only thing that doesn't work is 15M transmit, so I have been having fun with it on other bands for a week or so. I understand how L74 and C36 could "kill" the drive signal, but it looks like it would affect all bands - unless there is some weird series resonance going on that was close to 15M in my case. You can bet I will check those components the next time I take the radio apart. In all my troubleshooting processes, I made some photos and some resistance measurements that I would be glad to share with you. The photos show the repair process I used on the switch rivet problem. If you are interested, please send me your email address and I'll forward them to you as attachments. I think the size of the photo files are in the 250KB range, and the Excel spreadsheet is small. My email is k5gcw@...

I also followed WB5DX's comments with interest. However, since I had carefully measured the resistance of each individual switch contact during repair and after being reassembled (several times), I did not think that was my situation.

On 15M, I can get about 3-5 watts output, and there is a very broad peak when tuning the Drive Control - so broad that tuning L29 makes almost no difference at all. The 15M signal at TP4 actually appears to be

slightly stronger than on the other bands. Since the receiver works
well on 15M, logic seems to tell me that the problem could only be in
switch S1-7 or L29, but as you discovered, L74 and C36 are common to all
bands. Obviously, if I was smart enough, I would have found the problem
by now! So my logic is not that dependable!

Thanks for giving us the results of all your work Joan.

73, Bill, K5GCW

Hi everybody

For those interested in my original posting of the message, read
below.

I am assuming that no other person has seen this problem before,
except
Bill-K5GCW who got in contact with me and explained he has the same
problem with his 830, even after spending some considerable time
cleaning the wafer switches.
Well if you read this Bill, I have found the problem(s). If your
lucky,
it may be the same problem.

A recent posting by another Bill-WB5DX, who cleaned the switches with
de-oxid?? and has gone backwards in the process, may also be
interested
in reading this, because I think Bill may have disturbed the rivet
connections of the wafers, or maybe some cleaning material is lodged
in
the switch as it is difficult to get in there, or he may have even
bend
some of the contacts. Its not hard to do.

Anyway
I did as what most of you would do and that is to remove the RF board,

number each wafer, desolder each one and clean the switches and while
it's out, you also solder each wafer contact to the track of the
switch.
This requires a lot of patience and a bit of skill to reassemble and
realign all the switches before soldering them back on the board.
I found a number of contacts which were loose. The rivets were not
doing
their job anymore. The material must have shrunk a little. This is why

you have to solder them, if you want the 830 to be reliable.

Now in Australia I heard of a saying, that whenever something gets serviced (be it electronics or otherwise), they say that "it has gone in
for a grease and oil change".
It's a funny expression but when I pulled apart this wafer switch, I could relate to that. 2 of the switches had a liberal coating of a thick, greasy substance, and the RF board had a coating of what appears
to be oil. It was a big cleaning job.
But all the cleaning and soldering made absolutely no scrap of difference. Still very little output on 18MHz, and no ALC at all.
I lost track of the number of times I pulled that RF board out.
For those that havent worked on these, you can make only limited measurements because the way it's mounted, and access to the track side
of the board while it is switched on is near impossible.
I knew where the problem area was, except everything appears to be checking out. eg component values, connections, switches etc etc.
Then I found a bypass capacitor C74 which measured 500 Ohms I replaced

and with excitement put it together. I improved the output on 21 MHz considerably, but still not much happening on 18.
If you study the circuit, you will wonder how this capacitor could have
an affect on the output. (It all makes sense later on)
Then tonight, I finally had a breakthrough. I have been so close for days but missed it.
The neighbouring component to C74 is a RF choke L36. This choke has gone
nearly short. It measured 30uH with a large D factor. The original value
is 470uH.
Needless to say, I was very excited to have found it long last. I put it
all back together and aligned the RF board again and output on 18 MHz was finally achieved. Output on 21 MHz was also restored. All in all, a
good outcome.
I have learned a lot from this repair. One of them is that the circuit

from Kenwood has mistakes in it. One that led me on the wrong path for

some time until I checked the circuit board against circuit.
You know, I could have sworn it was going to be a band switch problem from all the symptoms it gave and I would have never guessed the faulty
components. When you check everything methodically and logically over and over and over again and it still dont work, you know your in a bit

of trouble.
So in the end, finding the problem, was it a fluke, lucky maybe? I dont

know. What I did learn, was to make no assumptions, lots of patience,
be
tenacious, dont doubt what you have learned in the past, how the
circuit
works and I can go on. I feel great about it and someone more
experienced may have done it in a tenth of my time, but you can never
put a price on what you learn. I am sure the owner of the rig will be
very happy too-No charge.
I know the story is a bit long winded, but I hope that for some of you

readers that may develop this fault later on in the rigs life, you
will
save some time repairing it and get it back on air asap.

Subject: RE: [TS-520_820_530_830] sp-230 vs sp-180

Ron,

Looking at the specification and the schematic, there is a switch which
selects a series capacitor and which rolls off the low frequency
response
(3dB point at 400Hz) and two switched inductors giving three
combunations
and which roll off the high frequency response (3dB points 1kHz, 1.5kHz
or
3KHz). With none of the switches selected then the response is
unfiltered.

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-02-07 22:15:43 UTC
From: Bill Scurlock
Topic: 6444 Message: 6658

Ron, I forgot to mention in my other email to be sure and check that the rig was modified to TX on 30M. There appear to be 2 ways to make the Tx modification - individual bands, or all 3 WARC bands at once.

Subject: RE: [TS-520_820_530_830] TS830S low power

Bill and Joan, thanks for posting all this information. My name is Ron and I have an 830 that I acquired which seems to have a similar symptom, in my case no drive and no power on 30m (receive ok). All other bands output ok, but some intermittent behavior that I am tentatively attributing to bandswitch problems. This rig had bad cathode resistors when I first got it so I made those repairs and have been just enjoying the rig for a while. But I am about ready to pull the covers off again and see if I can figure out the 30m problem. Bill I would appreciate if you would send your photos and other data to me at rhauser@...

Thanks!

Subject: Re: [TS-520_820_530_830] TS830S low power

Hi Joan. That's great that you found the problem(s). I struggled for a week or so after our last email, and then decided that I wanted to enjoy the radio for a while. The only thing that doesn't work is 15M transmit, so I have been having fun with it on other bands for a week or so. I understand how L74 and C36 could "kill" the drive signal, but it looks like it would affect all bands - unless there is some weird series resonance going on that was close to 15M in my case. You can bet I will check those components the next time I take the radio apart. In all my troubleshooting processes, I made some photos and some resistance measurements that I would be glad to share with you. The photos show the repair process I used on the switch rivet problem. If you are interested, please send me your email address and I'll forward them to you as attachments. I think the size of the photo files are in the

250KB range, and the Excel spreadsheet is small. My email is k5gcw@...

I also followed WB5DX's comments with interest. However, since I had carefully measured the resistance of each individual switch contact during repair and after being reassembled (several times), I did not think that was my situation.

On 15M, I can get about 3-5 watts output, and there is a very broad peak when tuning the Drive Control - so broad that tuning L29 makes almost no difference at all. The 15M signal at TP4 actually appears to be slightly stronger than on the other bands. Since the receiver works well on 15M, logic seems to tell me that the problem could only be in switch S1-7 or L29, but as you discovered, L74 and C36 are common to all bands. Obviously, if I was smart enough, I would have found the problem by now! So my logic is not that dependable!

Thanks for giving us the results of all your work Joan.

73, Bill, K5GCW

Subject: Re: [TS-520_820_530_830] TS830S low power

Hi everybody

For those interested in my original posting of the message, read below.

I am assuming that no other person has seen this problem before, except
Bill-K5GCW who got in contact with me and explained he has the same problem with his 830, even after spending some considerable time cleaning the wafer switches.
Well if you read this Bill, I have found the problem(s). If your lucky,
it may be the same problem.

A recent posting by another Bill-WB5DX, who cleaned the switches with de-oxid?? and has gone backwards in the process, may also be interested
in reading this, because I think Bill may have disturbed the rivet connections of the wafers, or maybe some cleaning material is lodged in
the switch as it is difficult to get in there, or he may have even bend
some of the contacts. Its not hard to do.

Anyway
I did as what most of you would do and that is to remove the RF board,

number each wafer, desolder each one and clean the switches and while it's out, you also solder each wafer contact to the track of the switch.
This requires a lot of patience and a bit of skill to reassemble and realign all the switches before soldering them back on the board.
I found a number of contacts which were loose. The rivets were not doing
their job anymore. The material must have shrunk a little. This is why

you have to solder them, if you want the 830 to be reliable.

Now in Australia I heard of a saying, that whenever something gets serviced (be it electronics or otherwise), they say that "it has gone in
for a grease and oil change".
It's a funny expression but when I pulled apart this wafer switch, I could relate to that. 2 of the switches had a liberal coating of a thick, greasy substance, and the RF board had a coating of what appears
to be oil. It was a big cleaning job.
But all the cleaning and soldering made absolutely no scrap of difference. Still very little output on 18MHz, and no ALC at all.
I lost track of the number of times I pulled that RF board out.
For those that havent worked on these, you can make only limited measurements because the way it's mounted, and access to the track side
of the board while it is switched on is near impossible.
I knew where the problem area was, except everything appears to be checking out. eg component values, connections, switches etc etc.
Then I found a bypass capacitor C74 which measured 500 Ohms I replaced

and with excitement put it together. I improved the output on 21 MHz considerably, but still not much happening on 18.
If you study the circuit, you will wonder how this capacitor could have
an affect on the output. (It all makes sense later on)
Then tonight, I finally had a breakthrough. I have been so close for days but missed it.
The neighbouring component to C74 is a RF choke L36. This choke has gone
nearly short. It measured 30uH with a large D factor. The original value
is 470uH.
Needless to say, I was very excited to have found it long last. I put it
all back together and aligned the RF board again and output on 18 MHz was finally achieved. Output on 21 MHz was also restored. All in all, a
good outcome.
I have learned a lot from this repair. One of them is that the circuit

from Kenwood has mistakes in it. One that led me on the wrong path for

some time until I checked the circuit board against circuit.
You know, I could have sworn it was going to be a band switch problem
from all the symptoms it gave and I would have never guessed the
faulty
components. When you check everything methodically and logically over
and over and over again and it still dont work, you know your in a bit

of trouble.
So in the end, finding the problem, was it a fluke, lucky maybe? I
dont
know. What I did learn, was to make no assumptions, lots of patience,
be
tenacious, dont doubt what you have learned in the past, how the
circuit
works and I can go on. I feel great about it and someone more
experienced may have done it in a tenth of my time, but you can never
put a price on what you learn. I am sure the owner of the rig will be
very happy too-No charge.
I know the story is a bit long winded, but I hope that for some of you

readers that may develop this fault later on in the rigs life, you
will
save some time repairing it and get it back on air asap.

6659. Dg-5 Hookup

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-02-08 04:03:13 UTC
From: naaah2001
Topic: 6659 Message: 6659

Hello All-
I will be recieving a DG-5 display for my TS-520se.
I do not expect that I will be recieving the hookup cables.
Could anyone tell me the procedure for wiring the unit to the
tranciever.
Will I be abled to fabricate the needed cables?
Also I have a TS 520 and TS 820.
Might this display be retro-fitted to be used on either of these?
(Just wondering)
Hopfully someone can help me or point me in the right direction!
Thanks To All!

6660. RE: [TS-520_820_530_830] TS-820S With No Plate Current Reading

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-02-08 05:19:51 UTC
From: Stephen Davis
Topic: 6457 Message: 6660

Hello All,

Update on my problematic TS-820S with no plate current reading and no bias reading. I have been pretty busy the last week so haven't had time to do much, however this weekend I will be able to spend some time on it. Seeking any and all advice on what to try next. I have the schematics, but translating that into useful troubleshooting information is not going so well. Maybe in a couple of years if I keep at it!! In the meantime, I have picked up some basic electronics books and an old book titled "How to Troubleshoot and Repair Amateur Radio Equipment". Now if I could just get a mind meld with the author!!

To recap the steps taken so far (Thanks to Walt for suggesting these!):

Checked the cathode resistors - tested OK
Checked the plate chokes for short - tested OK
Checked the relay on the relay board - contacts clean and I can see the relay work when I go from receive to send.
Checked the SG switch - OK
Filaments light in all three tubes.
Substituted all three tubes, no change in symptoms.
I took the following measurements at the bias pot.

Bias pot fully counterclockwise: left terminal -95v center terminal -105v right terminal -105v
Bias pot centered: left terminal -95v center terminal -95v right terminal -105v
Bias pot fully clockwise left terminal -95v center terminal -95v right terminal -105v

Note to Walt - I have the 1 watt 100kohm resistors that you suggested I pick up. Not sure what you wanted me to try with them.

Once again, I really appreciate all the suggestions and encouragement I have received so far from this group.

Steve K7QHU

Subject: RE: [TS-520_820_530_830] TS-820S With No Plate Current Reading

Hi Walt,

Your first paragraph is correct.

I took the following measurements at the bias pot.

Bias pot fully counterclockwise: left terminal -95v center terminal -105v right terminal -105v
Bias pot centered: left terminal -95v center terminal -95v right terminal -105v
Bias pot fully clockwise left terminal -95v center terminal -95v right terminal -105v

I took measurments with mode set to lsb, band set to 40 meters, mike gain down and with the send receive switch in the send position. All other controls set per the table in the manual for initial transmit tuning.

I am on the way to Radio Shack to pick up the resistors.

Thanks

Steve

Subject: Re: [TS-520_820_530_830] TS-820S With No Plate Current Reading

I am assuming the following. If I an wrong, please tell me.

With the rig keyed in SSB, mike gain down, meter in the IP position, no matter where you adjust the bias pot on the back of the rig you get no IP reading?

Assuming the above, with the rig keyed and set as above, Measure the voltage to ground on the terminal on each end of the Bias pot. Then place the meter on the center terminal and see if the voltage changes as you rotate this control. Give me readings with this full CCW, fully CW and center.

Unless you read 0 voltage on the center of the Bias pot in all positions, go to Radio Shack and get 3-100 K ohm resistors at 1 watt.Let me know when you have done this.

Vy 73, Walt.

Assunto: RE: [TS-520_820_530_830] TS-820S With No Plate Current Reading

Hello All,

Update on my problematic TS-820S with no plate current reading and no bias reading. I have been pretty busy the last week so haven't had time to do much, however this weekend I will be able to spend some time on it. Seeking any and all advice on what to try next. I have the schematics, but translating that into useful troubleshooting information is not going so well. Maybe in a couple of years if I keep at it!! In the meantime, I have picked up some basic electronics books and an old book titled "How to Troubleshoot and Repair Amateur Radio Equipment". Now if I could just get a mind meld with the author!!

To recap the steps taken so far (Thanks to Walt for suggesting these!):

Checked the cathode resistors - tested OK
Checked the plate chokes for short - tested OK
Checked the relay on the relay board - contacts clean and I can see the relay work when I go from receive to send.
Checked the SG switch - OK
Filaments light in all three tubes.
Substituted all three tubes, no change in symptoms.
I took the following measurements at the bias pot.

Bias pot fully counterclockwise: left terminal -95v center terminal -105v right terminal -105v

Bias pot centered: left terminal -95v center terminal -95v
right
terminal -105v
Bias pot fully clockwise left terminal -95v center terminal
-95v
right terminal -105v

Note to Walt - I have the 1 watt 100kohm resistors that you suggested I
pick
up. Not sure what you wanted me to try with them.

Once again, I really appreciate all the suggestions and encouragement I
have
received so far from this group.

Steve K7QHU

Subject: RE: [TS-520_820_530_830] TS-820S With No Plate Current Reading

Hi Walt,

Your first paragraph is correct.

I took the following measurements at the bias pot.

Bias pot fully counterclockwise: left terminal -95v center
terminal
-105v right terminal -105v
Bias pot centered: left terminal -95v center terminal -95v
right
terminal -105v
Bias pot fully clockwise left terminal -95v center terminal
-95v
right terminal -105v

I took measurments with mode set to lsb, band set to 40 meters,
mike
gain down and with the send receive switch in the send position. All
other
controls set per the table in the manual for initial transmit tuning.

I am on the way to Radio Shack to pick up the resistors.

Thanks

Steve

Subject: Re: [TS-520_820_530_830] TS-820S With No Plate Current Reading

I am assuming the following. If I an wrong, please tell me.

With the rig keyed in SSB, mike gain down, meter in the IP position, no matter where you adjust the bias pot on the back of the rig you get no IP
reading?

Assuming the above, with the rig keyed and set as above, Measure the voltage
to ground on the terminal on each end of the Bias pot. Then place the meter
on the center terminal and see if the voltage changes as you rotate this control. Give me readings with this full CCW, fully CW and center.

Unless you read 0 voltage on the center of the Bias pot in all positions, go
to Radio Shack and get 3-100 K ohm resistors at 1 watt.Let me know when you
have done this.

Vy 73, Walt.

6662. Re: [TS-520_820_530_830] TS-820S With No Plate Current Reading

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-02-08 12:47:59 UTC
From: Walt Breining
Topic: 6457 Message: 6662

With the rig turned off and the high voltage discharged, solder the 100 k resistors in series and solder one end of this string to the top of the plate choke (where the tube plates connect.) connect the other end to ground on the final cage. You can use a screw from the final cover and screw it down there. Leave the tubes in. Connect your + voltmeter lead one resistor up from ground and the voltmeter - lead to chassis Ground. Set your voltmeter to a scale that will read about 300 VDC. Do not hold the voltmeter or volt meter leads while doing this. Turn the power and filaments on, quickly note the meter reading, and turn the power off if the resistors start getting hot. If they do not, wait long enough for the filaments to warm up and see if you still get voltage. Discharge the High Voltage before you touch anything.

Actually, I should have told you to get 450 K ohm resistors as I have them running at about 2 watts here but that will be OK. Just turn the power on, get the reading, and turn the power off.

You should get something around 260v DC. this should be here as soon as you turn the power on. It could drop to 0 as the tubes warm up if there is a problem. If you read 0 volts after the first 10 seconds, do not even wait for the filaments to warm up, go ahead and kill the power to save the resistors.

This is very ball park. What we are trying to determine is whether high voltage is getting to the top of the plate choke. This forms a voltage / by 3 voltage divider so this test is not as dangerous as you will not have the full 800v on the volt meter or leads. The plate voltage will have to be way low or 0 to be the cause of no bias current.

The resistors will probably get hot and smell rather quickly. Be sure after you turn the power off to discharge everything before making contact with these components.

Let us know what you find out and we can go on from there.

Vy 73, Walt N9WB

6663. TS-520 CW FILTER

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-02-08 14:36:27 UTC
From: Gary
Topic: 6663 Message: 6663

I am looking for the CW filter for a TS-520S (Part# YG3395C)
Since this filter seems to be somewhat HARD to find, I wonder if anyone
has ever substituted another type filter for this rig??

If you have one, I sure would like to get it from you.

THANKS!!!
Gary - W5GNB

Hi Steve/Walt

1. This is a long shot but probably worth a mention.
I was sitting on some nos (new old stock) 6146 replacement tubes for some years before I had the opportunity to use them in a TS-520.
The tubes were of RCA brand with the following numbers on them - 6883B/8032A/8552.
These tubes are identical in appearance and performance as the 6146's, except they have 12 Volt filaments.
When I eventually used the tubes I got caught with my TS-520 not having any drive even though I could see some filaments glowing. Just not getting hot enough for emissions.
Suppose Steve bought the radio with a set of these in it, he will never get it going unless he rewires the tubes for 12V heater operation (and then place a big caution sign on the chassis, to remind yourself of the volt changes. You don't want to plug in a brand new set of 6Volt tubes).

2. From my recent repairs to a TS-830, I have made a few observations which may be useful if the 820 circuitry is similar.
a. Bias is independant of drive/ALC. I can de-tune the Drive control without affecting the bias setting.
b. Once the Drive control is peaked for maximum ALC, adjusting the bias pot will change the ALC reading somewhat.
c. You can not get an ALC reading if the 6146's are not installed. (The Anode cap does not have to be connected for an ALC reading though).
d. You can not get a bias reading if SG is switched off.

If I read Steve's comment correct, below, he has more than just a bias problem. He seems to be missing drive also if not getting any ALC reading.
Does Steve have another receiver to check if the oscillators are running and on frequency?
Does anyone else agree with that?
Have you followed Alvaro Py2FWA advise yet? (That is checking all the volages on the power supply board)

6665. RE: [TS-520_820_530_830] Dg-5 Hookup

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-02-08 14:47:25 UTC
From: Glenn Crawford
Topic: 6659 Message: 6665

Hi Norm, Common good quality audio/video patch cords with RCA phono plugs on each end will work for the three ?signal? cables. The power cable is a little different. If you can find two Remington electric shaver chords, cut off and discard the 120-volt plugs. Solder the two pieces together so there is a shaver plug on each end. The saver plugs make a near perfect fit to both the radio and the display. You may need to use a utility knife to cut a ?V? shaped notch in the plugs. Do not depend on the notch to force the correct polarity. Put a spot of red paint on the positive side of each plug and be very careful when connecting the two devices. You can make a power cord out of a piece of two-conductor (red/black) DC cable with proper sized female butt connectors on each end. Just be sure to observe proper polarity when connecting. I acquired a DG-5 display for my TS-520se with no cables and this approach has worked well for me. 73, Glenn W8EXX --- On Tue 02/07, naaah2001 < naaah2001@... > wrote: From: naaah2001 [mailto: naaah2001@...] To: TS-520_820_530_830@yahoogroups.com Date: Wed, 08 Feb 2006 04:03:13 -0000 Subject: [TS-520_820_530_830] Dg-5 Hookup Hello All-
I will be recieving a DG-5 display for my TS-520se.
I do not expect that I will be recieving the hookup cables.
Could anyone tell me the procedure for wiring the unit to the
tranciever.
Will I be abled to fabricate the needed cables?
Also I have a TS 520 and TS 820.
Might this display be retro-fitted to be used on either of these?
(Just wondering)
Hopfully someone can help me or point me in the right direction!
Thanks To All!
Norm

From: Stephen Davis
Topic: 6457 Message: 6666

All,

Thanks to all for the suggestions. I will be rolling up my sleeves, putting both hands in my pockets (safety first!) and tackle all the troubleshooting ideas you have given me. I will report back as I make progress. Thanks again.

Steve

Subject: Re: [TS-520_820_530_830] TS-820S With No Plate Current Reading

Hi Steve/Walt

1. This is a long shot but probably worth a mention.
I was sitting on some nos (new old stock) 6146 replacement tubes for some years before I had the opportunity to use them in a TS-520.
The tubes were of RCA brand with the following numbers on them - 6883B/8032A/8552.
These tubes are identical in appearance and performance as the 6146's, except they have 12 Volt filaments.
When I eventually used the tubes I got caught with my TS-520 not having any drive even though I could see some filaments glowing. Just not getting hot enough for emissions.
Suppose Steve bought the radio with a set of these in it, he will never get it going unless he rewires the tubes for 12V heater operation (and then place a big caution sign on the chassis, to remind yourself of the volt changes. You don't want to plug in a brand new set of 6Volt tubes).

2. From my recent repairs to a TS-830, I have made a few observations which may be useful if the 820 circuitry is similar.
a. Bias is independant of drive/ALC. I can de-tune the Drive control without affecting the bias setting.
b. Once the Drive control is peaked for maximum ALC, adjusting the bias pot will change the ALC reading somewhat.
c. You can not get an ALC reading if the 6146's are not installed. (The Anode cap does not have to be connected for an ALC reading though).
d. You can not get a bias reading if SG is switched off.

If I read Steve's comment correct, below, he has more than just a bias problem. He seems to be missing drive also if not getting any ALC reading.
Does Steve have another receiver to check if the oscillators are running

and on frequency?
Does anyone else agree with that?
Have you followed Alvaro Py2FWA advise yet? (That is checking all the
volages on the power supply board)

6667. Ts-830 VFO jumps and 9V dc line

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-02-10 09:20:36 UTC
From: i8vye
Topic: 6667 Message: 6667

If of interest for anybody, those are my experiences.

I have a ts-830 with external dfc-230 vfo. After many years the rig started the classic freqency jumps reported very often on the net.

I first strenghtend all ground screws, enforced ground return on AF-AVR boards, cleaned switches (fix and others) and cleaned the ext vfo plug (including the switch inside the plug). I also cleaned and lubrificated the wiper in the vfo variable capacitor. Bypassed the fix switch.

Everything seemed to be ok, but after few weeks, frequency jumps started again, even if less often.

I found two new, for me, sources of jumps:

1) trimmer cap on vfo unit (TC1), i cleaned it with a dry contact cleaner and rotated the control many times. Now it works, i have already purchased a new trimmer (6 Pf ceramic NP0) easy to find. As son as necessary i'll definitively substitute it. The allignement, after cleaning or substitution is easy and well descripted in the manuals.

2) all switches on 9 Vdc line are prone to instability even if well cleaned. In my case, the switches inside the dfc-230 are absolutely non reliable. You can clean them but first or later they will start giving trouble again. The check is easy: gently touch the switches while listening to a beat with cal on. If you ear frequency moving, one problem is there. All this is due to the fact that the 9Vdc is used as control line and also as supply to the internal vfo unit. So any slight instability on 9Vdc becomes a drift on internal vfo. My solution was to interrupt the 9Vdc to the internal vfo, install a dc regulator (used only for the VFO, a lm317 or 78xx to give 9.0 Vdc stabilized to the vfo.

Then i connected the 9VDc coming form the rig to a 1K resistor driving the base of 2n2222, the emitter to ground the collector to the coil of micro relay (normally open). The other coil of micro relay goes to

the
12Vdc. the normally opens contacts are connected: one to the output
of
the new dc regulator and the other on the remaining wire giving 9Vdc
to
the VFO unit (the one named VFB in the circuits). Now the original
9Vdc
are used only as control line, while there is a regulator devoted
only
to the VFO unit.

This way i didn't listen anylonger any frequency drift while
operating
switches belonging to the ts-830 or belonging to the external vfo.

73's de i8vye/0 (joe).

Hi:

Thank you Christ for the manual. I've been looking for it like a maniac
all day..

... oh, and hi everyone... new ham in the group here.

Alvin/N7SPY

6669. RE: [TS-520_820_530_830] TS-820S With No Plate Current Reading

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-02-11 01:48:59 UTC
From: Stephen Davis
Topic: 6457 Message: 6669

Hello Walt/Joan/Alvaro and all,

Walt, I did as you instructed and I measure about 270 volts one resistor up from ground in the voltage divider I constructed. The 270 volts appeared as soon as I switched power on. I left power on for about 10 seconds and the voltage held steady.

Alvaro, I checked R4 on the rectifier board and it was ok. I took a measurement at the point labeled SG (which I assume stands for Screen Grid) and it read -110 volts. The point labeled STB measured 110 volts, the point 210A was about 220 volts, the point 300A was about 300 volts and the point marked -C was -110 volts. Looking at the rectifier board, there are no burned components and it looks pretty clean.

Joan, I have the S2001A's in the rig, so the filament voltage should be okay.

To recap the problem, I get zero LP and zero ALC readings when going thru the tuning procedures. If I switch the meter to the HV position, it reads about 900 volts. Tuning into a dummy load confirms there is no output during the tuning procedure. By the way the radio receiver works great, its just the transmit side that's a little sick.

Thanks again for the help, and I will keep poking around (safely) until I hear from the group.

Steve K7QHU

Subject: Re: [TS-520_820_530_830] TS-820S With No Plate Current Reading

Hi Steve/Walt

1. This is a long shot but probably worth a mention.
I was sitting on some nos (new old stock) 6146 replacement tubes for some years before I had the opportunity to use them in a TS-520.
The tubes were of RCA brand with the following numbers on them - 6883B/8032A/8552.
These tubes are identical in appearance and performance as the 6146's, except they have 12 Volt filaments.
When I eventually used the tubes I got caught with my TS-520 not having any drive even though I could see some filaments glowing. Just not

getting hot enough for emissions.
Suppose Steve bought the radio with a set of these in it, he will never get it going unless he rewires the tubes for 12V heater operation (and then place a big caution sign on the chassis, to remind yourself of the volt changes. You don't want to plug in a brand new set of 6Volt tubes).

2. From my recent repairs to a TS-830, I have made a few observations which may be useful if the 820 circuitry is similar.
a. Bias is independant of drive/ALC. I can de-tune the Drive control without affecting the bias setting.
b. Once the Drive control is peaked for maximum ALC, adjusting the bias pot will change the ALC reading somewhat.
c. You can not get an ALC reading if the 6146's are not installed. (The Anode cap does not have to be connected for an ALC reading though).
d. You can not get a bias reading if SG is switched off.

If I read Steve's comment correct, below, he has more than just a bias problem. He seems to be missing drive also if not getting any ALC reading.
Does Steve have another receiver to check if the oscillators are running and on frequency?
Does anyone else agree with that?
Have you followed Alvaro Py2FWA advise yet? (That is checking all the volages on the power supply board)

6670. RES: [TS-520_820_530_830] TS-820S With No Plate Current Reading

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-02-11 12:11:44 UTC
From: PY2FWA
Topic: 6457 Message: 6670

Hello Davis,

Try to clean the relay on botton fo PA Unit, note that TS820S have 2
relays ..you don´t need open the cover of PA Unit, I will see the
schematic for more information about your problem

73

Alvaro

Assunto: RE: [TS-520_820_530_830] TS-820S With No Plate Current Reading

Hello Walt/Joan/Alvaro and all,

Walt, I did as you instructed and I measure about 270 volts one
resistor up from ground in the voltage divider I constructed. The 270
volts
appeared as soon as I switched power on. I left power on for about 10
seconds and the voltage held steady.

Alvaro, I checked R4 on the rectifier board and it was ok. I took
a
measurement at the point labeled SG (which I assume stands for Screen
Grid)
and it read -110 volts. The point labeled STB measured 110 volts, the
point
210A was about 220 volts, the point 300A was about 300 volts and the
point
marked -C was -110 volts. Looking at the rectifier board, there are no
burned components and it looks pretty clean.

Joan, I have the S2001A's in the rig, so the filament voltage
should be
okay.

To recap the problem, I get zero LP and zero ALC readings when
going
thru the tuning procedures. If I switch the meter to the HV position,
it
reads about 900 volts. Tuning into a dummy load confirms there is no
output
during the tuning procedure. By the way the radio receiver works great,

its
just the transmit side that's a little sick.

Thanks again for the help, and I will keep poking around (safely)
until I hear from the group.

Steve K7QHU

Subject: Re: [TS-520_820_530_830] TS-820S With No Plate Current Reading

Hi Steve/Walt

1. This is a long shot but probably worth a mention.
I was sitting on some nos (new old stock) 6146 replacement tubes for
some years before I had the opportunity to use them in a TS-520.
The tubes were of RCA brand with the following numbers on them -
6883B/8032A/8552.
These tubes are identical in appearance and performance as the 6146's,
except they have 12 Volt filaments.
When I eventually used the tubes I got caught with my TS-520 not having
any drive even though I could see some filaments glowing. Just not
getting hot enough for emissions.
Suppose Steve bought the radio with a set of these in it, he will never
get it going unless he rewires the tubes for 12V heater operation (and
then place a big caution sign on the chassis, to remind yourself of the
volt changes. You don't want to plug in a brand new set of 6Volt tubes).

2. From my recent repairs to a TS-830, I have made a few observations
which may be useful if the 820 circuitry is similar.
a. Bias is independant of drive/ALC. I can de-tune the Drive control
without affecting the bias setting.
b. Once the Drive control is peaked for maximum ALC, adjusting the bias
pot will change the ALC reading somewhat.
c. You can not get an ALC reading if the 6146's are not installed. (The
Anode cap does not have to be connected for an ALC reading though).
d. You can not get a bias reading if SG is switched off.

If I read Steve's comment correct, below, he has more than just a bias
problem. He seems to be missing drive also if not getting any ALC
reading.
Does Steve have another receiver to check if the oscillators are running

and on frequency?
Does anyone else agree with that?
Have you followed Alvaro Py2FWA advise yet? (That is checking all the
volages on the power supply board)

6671. RES: [TS-520_820_530_830] TS-820S With No Plate Current Reading

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-02-11 12:19:10 UTC
From: PY2FWA
Topic: 6457 Message: 6671

Davis, on the Kenwood site you can download some service notes for
TS820S....please go there and download these documents...
ASB0024C and ASB0024D these documents still have some important
information about transmition faults....

Assunto: RE: [TS-520_820_530_830] TS-820S With No Plate Current Reading

Hello Walt/Joan/Alvaro and all,

Walt, I did as you instructed and I measure about 270 volts one
resistor up from ground in the voltage divider I constructed. The 270
volts
appeared as soon as I switched power on. I left power on for about 10
seconds and the voltage held steady.

Alvaro, I checked R4 on the rectifier board and it was ok. I took
a
measurement at the point labeled SG (which I assume stands for Screen
Grid)
and it read -110 volts. The point labeled STB measured 110 volts, the
point
210A was about 220 volts, the point 300A was about 300 volts and the
point
marked -C was -110 volts. Looking at the rectifier board, there are no
burned components and it looks pretty clean.

Joan, I have the S2001A's in the rig, so the filament voltage
should be
okay.

To recap the problem, I get zero LP and zero ALC readings when
going
thru the tuning procedures. If I switch the meter to the HV position,
it
reads about 900 volts. Tuning into a dummy load confirms there is no
output

during the tuning procedure. By the way the radio receiver works great, its
just the transmit side that's a little sick.

Thanks again for the help, and I will keep poking around (safely)
until I hear from the group.

Steve K7QHU

Subject: Re: [TS-520_820_530_830] TS-820S With No Plate Current Reading

Hi Steve/Walt

1. This is a long shot but probably worth a mention.
I was sitting on some nos (new old stock) 6146 replacement tubes for
some years before I had the opportunity to use them in a TS-520.
The tubes were of RCA brand with the following numbers on them -
6883B/8032A/8552.
These tubes are identical in appearance and performance as the 6146's,
except they have 12 Volt filaments.
When I eventually used the tubes I got caught with my TS-520 not having
any drive even though I could see some filaments glowing. Just not
getting hot enough for emissions.
Suppose Steve bought the radio with a set of these in it, he will never
get it going unless he rewires the tubes for 12V heater operation (and
then place a big caution sign on the chassis, to remind yourself of the
volt changes. You don't want to plug in a brand new set of 6Volt tubes).

2. From my recent repairs to a TS-830, I have made a few observations
which may be useful if the 820 circuitry is similar.
a. Bias is independant of drive/ALC. I can de-tune the Drive control
without affecting the bias setting.
b. Once the Drive control is peaked for maximum ALC, adjusting the bias
pot will change the ALC reading somewhat.
c. You can not get an ALC reading if the 6146's are not installed. (The
Anode cap does not have to be connected for an ALC reading though).
d. You can not get a bias reading if SG is switched off.

If I read Steve's comment correct, below, he has more than just a bias
problem. He seems to be missing drive also if not getting any ALC
reading.
Does Steve have another receiver to check if the oscillators are running

and on frequency?
Does anyone else agree with that?
Have you followed Alvaro Py2FWA advise yet? (That is checking all the

volages on the power supply board)

6672. Display DG-1 of TS-820S again....

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-02-11 13:27:29 UTC
From: py2fwa
Topic: 6672 Message: 6672

Hi Group....

I still have some problems with my DG-1 display of TS-820S, sprayed deoxit
on the contacts, washed the PCB, resold all components etc...but the problem still continue. Some person of this group already made this modification using the
dysplay like this == http://www.aade.com/Applic~1.htm#TS820 ???
I believe that this is a soluction finnal for the DG-1 problems. Some suggestion are wellcome.

73 for all and sorry for my poor English....

OK, we know that you are getting plate voltage. With everything discharged, Take the plate caps off of the tubes and check for continuity with your ohm meter between the top of the plate choke and the plate cap. I just want to confirm that High voltage can get from the top of the plate choke to the tubes. I know that this is unlikely, but we are to the point where we need to be thorough.

Since you cannot get bias current no matter where the bias control is set, You have a problem in the final stage. Even if you had no drive and no output from the 12BY7 tube, if the final stage were working properly you should be able to get some idle current. This would even be true with weak tubes.

We now have confirmed that you are getting B+ to the tube plates.
Next you need to look into the Screen Grid voltage.

Whoa Hold the phone Mildred!

You got MINUS 110 v on the screen? WRONG. Minus 110 volts on the screen will shut the tube off and keep it from conducting. Be sure you are reading it right. Black volt meter on ground red volt meter lead on SG post.

Be SURE that the SG switch on the back is ON.

If your problem turns out to be one of the above and you actually are getting something like + 200 V on the SG point with the mode switch in SSB then measure the voltage at pin 3 at each tube socket on the foil side of the board. This is to confirm that about + 200 volts is going to the screen pin, pin 3.

If Minus 110 is actually what you are getting at the SG terminal, then go to the SG switch and carefully measure the 3 terminals on it. The top terminal should have something on it like + 200, the center should be + 200 the bottom -110. This is with the SG switch ON.

If you have trouble counting the pins, tell me and I will walk you through it.

6674. Some more thoughts on matched valves

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-02-11 15:41:30 UTC
From: Joan de vk5kyo
Topic: 6457 Message: 6674

Hi everybody

I know there has been lots of discussions in the past regarding matched pairs of 6146's for the Kenwoods and alike, and the answer may have already been posted, but I have just repaired 2 TS-830's with output power problems which left me with some questions.
During the quest to resolve the issues, I was thinking a little more on the issue of matched valves.
The owner of the radio I was repairing, send me a matched pair of 6146's and on each of the valves was a number written on it.
Can I assume this is the gain of the tube, or is it the current drawn under certain test parameters, and the fact that both numbers are the same, I will say that they are a match?
The other question I was left pondering with is when I pulled my RCA test tubes out (which happens to have 12 volt filaments), and rewired the set back to standard 6 volt operation, will it be as good?
When the experts check new tubes for so called matched characteristics, are they applying 6volts to each filament and testing the gain of a tube individually, or are they putting a pair of tubes with their heater filaments in series (as Kenwood is wired this way), and then checking for their individual gain.
The results will be different and for those that know, can you tell me if it is significant or not.
The reason why I say it will be different is because my experience has been that the filament of each 6146 is not exactly the same resistance(call it manufacturers tolerance), and if you measure the voltage drop across each tube, it maybe 6.0 volts for one and 6.4 volts for the other. That is pretty well what I measure.
This is a bad thing because the tube with a higher resitance will also have a higher voltage drop across the heater and will therefore be more stressed.
Which begs the question whether it will be working harder than it's mate who is having a holiday.
I know the valves will still work and more than likely put out 100++ Watts, but it does sort of blow the matched pair theory.
I'd would call them truly matched if both the filaments have equal resistance and therefore hopefully the same heat value generated to promote emissions and finally they have the same gain.
If the tubes were only tested individually with 6 volts applied to the heaters, then the only way we could correct the problem, is to balance out the weaker valve with a bit of extra resistance parallel with the heater so that both 6146's will have equal heater voltage.
I hope you get the drift of what I am trying to say.
I'd appreciate your thoughts on this.
One might say that it is too much theory and that in the practical sense

it wont make a scrap of difference.
It may well be the reason why there have been some premature failures, especially when one starts to mix different brands of 6146's.
Illustration time - Different manufacturers of clothing are all asked to produce a size 16 garment, and yet the final product all seem to differ a little in size.
To stay on the humurous side, my last statistic count of 5, goes to the most popular name in this group, and that is"Bill". The Bill's have it.
Because of this fact, I like to drag these wonderful gentlemen into another illustration, and say that allthough they carry the same name, all Bills are not the same, in fact they are all unique.
So how can you ever have matched pairs of 6146's??

Joan VK5KYO

6676. Replacement Relay for TS-820s

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-02-11 16:21:04 UTC
From: Irv
Topic: 6676 Message: 6676

I am trying to help out an oldtimer here who has
a TS-820. The relay is the one which switches the
IF and other circuitry between transmit and receive
(not the antenna relay). I've cleaned it once before,
but he's a heavy smoker and that may have influenced
the problem. I've cleaned a number of them on
previous occasions (I used to have an 820 as well), and
am pretty sure that with time I'm going to have to
find replacements.

Ive already referred him to Ken's Electronics and
he will call them monday. I have also searched around
including this group but can't find the info I need.
Hopefully I'll get it here.

Does anyone know of other sources for replacement and
the part number (of the replacement) if possible?

Thanks in advance for any assistance.

6677. Current surge

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-02-11 17:01:54 UTC
From: Kim
Topic: 6677 Message: 6677

My TS 830S was damaged by a current surge. A few components were burned on the IF board and a few on the RF board. The radio no longer transmits but still receives. I'n not sure if the cause is in the voltage regulation circuitry or if current was drawn from a failure near the tubes. Any suggestions?

6679. RE: TS-820S With No Plate Current Reading

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-02-11 20:24:56 UTC
From: pjcoombs@frontiernet.net
Topic: 6457 Message: 6679

Steve,

Take that reading again on the screen grid voltage. I'm pretty sure it should be a positive number. Make sure you are reading from the voltage divider junction to ground and not across one of the resistors.

-jay, kb9wwq

> I took a measurement at the point labeled SG
>(which I assume stands for Screen Grid)
>and it read -110 volts.

6680. RE: [TS-520_820_530_830] TS-820S With No Plate Current Reading

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-02-11 23:34:42 UTC
From: Stephen Davis
Topic: 6457 Message: 6680

Hello gang,

Thanks for all the suggestions. Here are the results of the latest testing. First I verified the SG reading by doing the following:

Okay, to measure the SG point on the Rectifier board I set up the VOM as follows: Black lead plugged into the VOM socket labeled "- com" and the other end of the black lead is clipped to the chassis (ground) of the radio. The red lead is plugged into the socket labeled " + v o m" (the o is really the ohms sign). I use the other end to the red lead to carefully measure the point SG. When I measure the point SG with the red lead, it deflects the needle below the zero reading. Next, I reverse the lead by clipping the red lead to ground and measuring point SG with the black lead and it measures 110 volts. I interpret this as being negative 110 volts.

I also noticed a measurement point labeled SG on the Final board. If I take a measurement here (SG point on the final board) then the reading is positive 250 volts.

Next measurement was to measure the SG test point on the final board and pin 3 of the final tubes with the SG switch ON and the mode switch in the TUNE position. Both pin 3's and the SG test point measured 0 volts

Next measurement was to measure the SG test point on the final board and pin 3 of the final tubes with the SG switch ON and the mode switch in the LSB position. Both pin 3's and the SG test point measured Positive 250 volts.

Perhaps I confused the issue when I took the negative readings at the SG test point on the Rectifier board!

Alvaro, you mentioned a relay on the bottom of the PA board. I don't see a relay there. I do see a metal box that is between the back of the chassis and the PA board (right next to the SG switch). Could this be the relay?

Thanks again for all the help.

Steve - K7QHU

Subject: Fw: [TS-520_820_530_830] TS-820S With No Plate Current Reading

Steve: The voltage on Pin 3 of each 6146 must be positive in the 200-250 volt range. If it is minus or negative your finals will not work correctly.

Black voltmeter probe to chassis ground - red probe to Pin 3. Meter set to its highest DV volt range until it is safe to use a lower range. Set meter to read positive voltages. SG switch ON Good luck.

Joe k7mks

6681. RES: [TS-520_820_530_830] TS-820S With No Plate Current Reading

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-02-12 00:07:30 UTC
From: PY2FWA
Topic: 6457 Message: 6681

Hi Steve, the TS-820S use 2 relay.

One of them are next to the side botton of PA Unit....into a metal box (Blindage) .free 2 screws to have access to this relay, is very easy to find it.

73

Alvaro

Assunto: RE: [TS-520_820_530_830] TS-820S With No Plate Current Reading

Hello gang,

Thanks for all the suggestions. Here are the results of the latest testing. First I verified the SG reading by doing the following:

Okay, to measure the SG point on the Rectifier board I set up the VOM as follows: Black lead plugged into the VOM socket labeled "- com" and the other end of the black lead is clipped to the chassis (ground) of the radio.
The red lead is plugged into the socket labeled " + v o m" (the o is really
the ohms sign). I use the other end to the red lead to carefully measure
the point SG. When I measure the point SG with the red lead, it deflects
the needle below the zero reading. Next, I reverse the lead by clipping
the red lead to ground and measuring point SG with the black lead and it measures 110 volts. I interpret this as being negative 110 volts.

I also noticed a measurement point labeled SG on the Final board. If I take
a measurement here (SG point on the final board) then the reading is positive 250 volts.

Next measurement was to measure the SG test point on the final board and pin
3 of the final tubes with the SG switch ON and the mode switch in the TUNE

position. Both pin 3's and the SG test point measured 0 volts

Next measurement was to measure the SG test point on the final board and pin
3 of the final tubes with the SG switch ON and the mode switch in the LSB
position. Both pin 3's and the SG test point measured Positive 250 volts.

Perhaps I confused the issue when I took the negative readings at the SG test point on the Rectifier board!

Alvaro, you mentioned a relay on the bottom of the PA board. I don't see a
relay there. I do see a metal box that is between the back of the chassis
and the PA board (right next to the SG switch). Could this be the relay?

Thanks again for all the help.

Steve - K7QHU

Subject: Fw: [TS-520_820_530_830] TS-820S With No Plate Current Reading

Steve: The voltage on Pin 3 of each 6146 must be positive in the 200-250 volt range. If it is minus or negative your finals will not work correctly.

Black voltmeter probe to chassis ground - red probe to Pin 3. Meter set to
its highest DV volt range until it is safe to use a lower range. Set meter
to read positive voltages. SG switch ON Good luck.

6682. RES: [TS-520_820_530_830] TS-820S With No Plate Current Reading

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-02-12 00:16:44 UTC
From: PY2FWA
Topic: 6457 Message: 6682

Steve,

I will upload a picture of this relay on ts820s

73

Alvaro
PY2FWA

Assunto: RE: [TS-520_820_530_830] TS-820S With No Plate Current Reading

Hello gang,

Thanks for all the suggestions. Here are the results of the latest
testing. First I verified the SG reading by doing the following:

Okay, to measure the SG point on the Rectifier board I set up the VOM as
follows: Black lead plugged into the VOM socket labeled "- com" and the
other end of the black lead is clipped to the chassis (ground) of the
radio.
The red lead is plugged into the socket labeled " + v o m" (the o is
really
the ohms sign). I use the other end to the red lead to carefully
measure
the point SG. When I measure the point SG with the red lead, it
deflects
the needle below the zero reading. Next, I reverse the lead by
clipping
the red lead to ground and measuring point SG with the black lead and it
measures 110 volts. I interpret this as being negative 110 volts.

I also noticed a measurement point labeled SG on the Final board. If I
take
a measurement here (SG point on the final board) then the reading is
positive 250 volts.

Next measurement was to measure the SG test point on the final board and
pin
3 of the final tubes with the SG switch ON and the mode switch in the
TUNE
position. Both pin 3's and the SG test point measured 0 volts

Next measurement was to measure the SG test point on the final board and pin
3 of the final tubes with the SG switch ON and the mode switch in the LSB
position. Both pin 3's and the SG test point measured Positive 250 volts.

Perhaps I confused the issue when I took the negative readings at the SG test point on the Rectifier board!

Alvaro, you mentioned a relay on the bottom of the PA board. I don't see a
relay there. I do see a metal box that is between the back of the chassis
and the PA board (right next to the SG switch). Could this be the relay?

Thanks again for all the help.

Steve - K7QHU

Subject: Fw: [TS-520_820_530_830] TS-820S With No Plate Current Reading

Steve: The voltage on Pin 3 of each 6146 must be positive in the 200-250 volt range. If it is minus or negative your finals will not work correctly.

Black voltmeter probe to chassis ground - red probe to Pin 3. Meter set to
its highest DV volt range until it is safe to use a lower range. Set meter
to read positive voltages. SG switch ON Good luck.

6683. RE: [TS-520_820_530_830] TS-820S With No Plate Current Reading

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-02-12 00:33:21 UTC
From: Stephen Davis
Topic: 6457 Message: 6683

Hi Alvaro,

I found it, thanks. The contacts look clean. When I switch from receive to send (function switch in the TUNE position) I can see the contacts closing. So it seems to be working. Is there a secret to removing the plasic cover. I don't want to break it.

Thanks

Steve K7QHU

Subject: RES: [TS-520_820_530_830] TS-820S With No Plate Current Reading

Hi Steve, the TS-820S use 2 relay.

One of them are next to the side botton of PA Unit....into a metal box (Blindage) .free 2 screws to have access to this relay, is very easy to find it.

73

Alvaro

Assunto: RE: [TS-520_820_530_830] TS-820S With No Plate Current Reading

Hello gang,

Thanks for all the suggestions. Here are the results of the latest testing. First I verified the SG reading by doing the following:

Okay, to measure the SG point on the Rectifier board I set up the VOM as follows: Black lead plugged into the VOM socket labeled "- com" and the other end of the black lead is clipped to the chassis (ground) of the radio.
The red lead is plugged into the socket labeled " + v o m" (the o is really

the ohms sign). I use the other end to the red lead to carefully measure
the point SG. When I measure the point SG with the red lead, it deflects
the needle below the zero reading. Next, I reverse the lead by clipping
the red lead to ground and measuring point SG with the black lead and it
measures 110 volts. I interpret this as being negative 110 volts.

I also noticed a measurement point labeled SG on the Final board. If I take
a measurement here (SG point on the final board) then the reading is
positive 250 volts.

Next measurement was to measure the SG test point on the final board and pin
3 of the final tubes with the SG switch ON and the mode switch in the TUNE
position. Both pin 3's and the SG test point measured 0 volts

Next measurement was to measure the SG test point on the final board and pin
3 of the final tubes with the SG switch ON and the mode switch in the LSB
position. Both pin 3's and the SG test point measured Positive 250
volts.

Perhaps I confused the issue when I took the negative readings at the SG
test point on the Rectifier board!

Alvaro, you mentioned a relay on the bottom of the PA board. I don't see a
relay there. I do see a metal box that is between the back of the chassis
and the PA board (right next to the SG switch). Could this be the
relay?

Thanks again for all the help.

Steve - K7QHU

Subject: Fw: [TS-520_820_530_830] TS-820S With No Plate Current Reading

Steve: The voltage on Pin 3 of each 6146 must be positive in the 200-250
volt range. If it is minus or negative your finals will not work
correctly.

Black voltmeter probe to chassis ground - red probe to Pin 3. Meter set
to

its highest DV volt range until it is safe to use a lower range. Set
meter
to read positive voltages. SG switch ON Good luck.

Joe k7mks

6684. MC-50 mic

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-02-12 03:03:57 UTC
From: Bill
Topic: 1307 Message: 6684

Does anyone happen to have (or know of) an MC-50 mic available. I prefer to find one that lacks a little in cosmetics (but works fine) to save on costs. Thanks - Bill

6685. Re: [TS-520_820_530_830] MC-50 mic

Bill,

There is one for sale on www.qth.com for 55.00 plus 8.00 shipping.
Based on previous eBay prices this is an ok deal.

Steve K7QHU

6687. Re: MC-50 mic

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-02-12 03:47:44 UTC
From: Bill
Topic: 1307 Message: 6687

Thanks! Yes, I have been watching Ebay and other swap forums, and can't quite get one for my budjet, which is why I mentioned the cosmetics. If I find one that was in a drawer, box, closet, etc, and a little scratched up but working, I could possibly get it a little cheaper. You know, I'm the typical ham!

I missed one on Ebay a few weeks back. It was beat up, but was advertised as working perfectly, and it went for $30. Assuming they were truthful about the functional parts, that was a pretty good deal. There have been others just about as close, but I missed them.

I'm not in any hurry, as my 830 is slated for surgery in a week or so (see previous postings). Thanks - Bill

6688. Re: [TS-520_820_530_830] TS-820S With No Plate Current Reading

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-02-12 04:41:23 UTC
From: Walt Breining
Topic: 6457 Message: 6688

OK You are almost there. You get + 250 volts on the SG point on the final board but 0V on pin 3 of the tubes.

First, be sure that you are counting the pins correctly and you are not getting the 0V reading from pin 6. Pin one is connected to pin 4 and 6 by foil. From pin 1 count clockwise to pin 3 looking at the foil side of the board.

If you are getting 0V on pin 3 the correct voltage of + 250V is not getting to pin 3 so you have no screen voltage shutting the tube down. On the foil side of the board, orient the board so the SG pin is at the bottom. The foil that the SG pin connects to goes up and curves to the right. Just above this is another strip of foil. This strip should also have +250 V. On the top (component) side of the board, a choke coil (L2) connects these two pieces of foil together. From the second foil, a 100 ohm resistor (R6) is on top of the board going from this second foil to the foil that connects to pin 3 of one of the tubes. Again from this second foil, a jumper wire on the top of the board goes to a piece of foil on the left end of the board that connects to another 100 ohm resistor R5 that is on top of the board. This resistor goes to foil that connects to pin 3 of the other tube. Something in this circuit is open keeping the + 250 V from reaching the tubes. My first suspect will be that the choke coil L2 is open. You can unplug the rig, remove the tubes, and check L2 for continuity with your ohm meter. It should show a short of 0 ohms. Be sure to discharge both the HV and the SG pins to grounds before doing this or you can hurt yourself or fry the ohm meter.

Be sure after checking the ohms to return the meter to a voltage position so you do not later accidentally hook it to voltage while in the ohms X 1 position or you will smoke the meter.

Now if you do find that the choke is defective, get back to me before replacing it. Something else will be bad that caused it to open.

If you find that you were measuring the wrong tube pins, disregard the above, measure the correct pins and tell me what they read.

Vy 73, Walt N9WB

6689. RE: [TS-520_820_530_830] TS-820S With No Plate Current Reading

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-02-12 04:56:38 UTC
From: Stephen Davis
Topic: 6457 Message: 6689

Hi Walt,

I took two measurements under different conditions on pin 3 of the finals and the SG test point on the final board.

The first measurement was done with the function switch in the LSB position. In this scenario, I measure about 250 volts on the pin 3's and 250 volts on the SG test point.

The second measurement was done with the function switch in the TUNE position. In this scenario I measure Zero volts on the pin 3's and Zero volts on the SG test point.

So it seems that switching the mode switch from LSB to TUNE causes the loss of voltage on pin 3 of the final tubes and at the SG test point. This may be normal, but I am not sure.

Thanks for your patience and help.

Steve K7QHU

Subject: Re: [TS-520_820_530_830] TS-820S With No Plate Current Reading

OK You are almost there. You get + 250 volts on the SG point on the final board but 0V on pin 3 of the tubes.

First, be sure that you are counting the pins correctly and you are not getting the 0V reading from pin 6. Pin one is connected to pin 4 and 6 by foil. From pin 1 count clockwise to pin 3 looking at the foil side of the board.

If you are getting 0V on pin 3 the correct voltage of + 250V is not getting to pin 3 so you have no screen voltage shutting the tube down. On the foil side of the board, orient the board so the SG pin is at the bottom. The foil that the SG pin connects to goes up and curves to the right. Just above this is another strip of foil. This strip should also have +250 V. On the top (component) side of the board, a choke coil (L2) connects these two pieces of foil together. From the second foil, a 100 ohm resistor (R6) is on top of the board going from this second foil to the foil that connects to pin 3 of one of the tubes. Again from this second foil, a jumper wire on the top of the board goes to a piece of foil on the left end of the board that connects to another 100 ohm resistor R5 that is on top of the board. This resistor

goes to foil that connects to pin 3 of the other tube. Something in this circuit is open keeping the + 250 V from reaching the tubes. My first suspect will be that the choke coil L2 is open. You can unplug the rig, remove the tubes, and check L2 for continuity with your ohm meter. It should show a short of 0 ohms. Be sure to discharge both the HV and the SG pins to grounds before doing this or you can hurt yourself or fry the ohm meter.

Be sure after checking the ohms to return the meter to a voltage position so you do not later accidentally hook it to voltage while in the ohms X 1 position or you will smoke the meter.

Now if you do find that the choke is defective, get back to me before replacing it. Something else will be bad that caused it to open.

If you find that you were measuring the wrong tube pins, disregard the above, measure the correct pins and tell me what they read.

Vy 73, Walt N9WB

6691. RE: [TS-520_820_530_830] TS-820S With No Plate Current Reading

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-02-12 18:01:30 UTC
From: Stephen Davis
Topic: 6457 Message: 6691

Hi Walt,

With the function switch in CW mode, I measure 250 volts on the pin 3's of the final and 250 volts on the SG test point. Note in making all these measurements, the send/receive switch remains in the receive position. I have not tried to take any measurements with the send/receive switch in the send position.

Thanks

Steve K7QHU

From: TS-520_820_530_830@yahoogroups.com [mailto:TS-520_820_530_830@yahoogroups.com] On Behalf Of Walt Breining

Subject: Re: [TS-520_820_530_830] TS-820S With No Plate Current Reading

What about CW?

From: pchapman9202003
Topic: 6579 Message: 6692

That leaves me out since I have no gutters on this house. With 28
exterior walls, I went with drip edge, HI

Like birds on a high voltage line do not have arms to touch the
other side. My only regret is that squirrels need longer arms.

6695. Re: TS-830 w/audio problem

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-02-13 01:32:09 UTC
From: Bill
Topic: 6580 Message: 6695

Thanks for reminding me. I did get some DeoxIt (at Frys) and used
it on all the audio component connections that looked like might
affect the problem. Well, it turned out to not be the af - pot.
But, rather, the headphone jack in the back. I simply spayed a
small amount of the product in the jack (placing a paper towel on
the otherside to prevent it spitting all over the inside pc board).
And that did it! No further fading or crackles in the audio.

Of course, there after I had the output problem and the rig was
scheduled for band switch surgery anyway - so I don't have it right
now. Thanks for everyone's help.

Now to find a cheap mc-50 mic!

73, Bill

Hi Dennis

Just a quick note.
It baffles me that you get the messages I post and yet, right now I still havent received a ping of my own message.
Something odd going on.
Dennis, the consenses are that matched pairs are not really an issue for radio but more so for audio amplifiers so that crossover distortion is minimised.
But I thought I put it to the group and see what they thought about matching the filament voltage, so that at least each valve has a better change of pulling the load and may give more longevity, or if it is a real bad match, one that is stressed is surely wide open to premature failure.
I was also interested if anybody knew how the matching process was achieved. I suspect it is on a valve by valve basis.
I suspect my theory of different filament resistances wouldthen totally upset the matching theory if filaments are put in series as is done in the Kenwoods.
I am going North for work tomorrow, about 180km and I am hoping to get a HF going on the work 4WD. While the other person is doing their survey work, I might get time to do some wiring. I might be able to have a QSO with you sometime. Most our sites are on hilltops to take off should be good.
Anyway, got to pack those 830's and send them back.

73 for now

Joan

I am not a moderator here but I am on some other groups.

These are my thoughts on the subject...

The use of reply is normal and expected. But the trimming
of posts to reduce the amount sent but leaving enough content
for the subject at hand is very important. The is especially
true of digests. At the very least it helps to remove all the
Yahoo inserted fluff. Not everyone has highspeed internet
access. I enjoy my T3 access while at work but living in a rural
area DSL and cable are not available. Dialup is slow at best and
the other options are expensive.

73,
Jon

If you could identify the specific components, that would help. I'd
look very carefully at all power supply voltages. I'm surprised you had
a current surge, and now it's operating normally. What were the
circumstances when the surge occurred?

6702. Re: [TS-520_820_530_830] Re: Some more thoughts on matched valves

For 520, 530, 820, 830, or any rig that uses a pair of 6146's in parallel in the final, it makes no difference if they are "matched" or not. As long as they are reasonably close in performance (not one weak and one good one, etc.) and they are identical in number (pair of A's, pair of W's, etc.). they should work fine. Trying to find or paying for "matched" tubes that are used in a parallel combination is a waste of time and money. There is no benefit.

From: wb4ouf
Topic: 6703 Message: 6703

Well, I tried everything suggested. I disassembeld the DG-1 and was really shocked to see the poor solder job that was done during manufacture. I am the original owner, so I know no one has been in there. I did re-solder all the connections with a 25W iron and, was very careful with that task. Cleaned everything up, checked for solder bridges, re-assembled and voila!..... blank display. Same as before. Seems like it may be a component failue but, I am puzzled by the fact that there is absolutely no display..... it's out completely and the 5V supply is OK. Lack of test equipment limits my ability to go further but, thanks to all that had suggestions..... May just disassemble again and see if I missed anything. Thank you and wish me luck... PS: anyone got a DG-1 for sale??
73s, Frank

The radio was turned on with the heater switch off and was not being
used. I smelled a burning smell and quickly unplugged it. The burned
components are R203 2W metal film resistor and the 330V electrolytic
caps next to it on the IF board. On the RF board it's a few of the
slug tuned coils on the last row closest to the finals cage.
It's not transmitting but still receives fine. Hope that helps. Kim

6705. TS 520 unstable meter

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-02-14 00:40:20 UTC
From: wayneg
Topic: 6705 Message: 6705

Trying to figure out why the meter sometimes drops to zero while transmitting and output still holds steady. It will usually show accurate readings while loading into a dummy load but on occasion the meter will not move so I load it according to my Autek watt/swr meter. Normally when start transmitting it will gradually start moving. A few minutes ago was transmitting with 50 watts output according to the Autek meter and was showing 160 ma on the rig meter. The meter deflection later may slowly drop and go to zero ma but the Autek meter will still show a steady 50 watts out then it will probably come right back up to 160 ma? The meter deflection on receive is always fine and will always shows an accurate deflection.

Any ideas or suggestions?
Thanks.
Wayne, NM3B

There is a adjustment pot on the side for this meter setting in the RF mode. It is called the RF volt control. It is on page 13 of the manual. Clean this control using De Oxit or rubbing alcohol.

You could also clean the multimeter switch. This is the switch that changes the meter between ALC,IP,RF,HV.

Does it do this in the IP, or HV position or Just RF?

Thanks for the information and will certainly try DeOxit.
Bought this rig about a month ago and want to get all the "bugs" out
of it. It is in beautiful condition but imagine it set around for a
while not being used and that is never any good for a tube rig. I
have been operating it steady and that is the only problem I found.
Thanks also for the neutralizing tips of a week ago and worked out
fine. Have been running it pretty steady this morning on 40 meters
and meter has been holding fine so maybe a little DeOxit will do the
trick so to speak and plan to use that this afternoon when I get back
from Rat Shack.
Thanks again.

Topic: 6709 Message: 6709

Thanks to all who replied. I received the following info from
Cliff Holland, KA5IPF:

Go to http://www.kenselectronics.com/lists/relays.htm and down toward
the bottom he has listed a direct replacement. I haven't tried it but
was given the info by someone who had and was satisfied.

I went to the link Cliff game me -- Ken's Electronics, and
found the following info...

MH4P-12VDC-300 ohm Omron Kenwood T599D,
TS820 S51-4031-05, use 401013-S

401013-S term 12VDC F.BV.153-b31/103, replaces
MH4P-12VDC-300ohm in T599D & TS-820 $18.00

I guess this is the place to try.

Thanks again for all the help in leading me to this -- I think
it's our last chance! Special thanks again to Cliff!

Thanks Irv,

And to the group. I called Ken's and ordered the replacement relay for the TS-820S...cost $18.00 plus shipping by US mail.

I wanted to check the T/R relay in the TS-820S and can't seem to locate it. Anyone got a suggestion as how to find it? Saw a small metal square box. Didn't have time to dig further. Wanted to check contacts on it too while I have it open.

...to all who hold similar thoughts on the message threads. Some simple cut and paste will eliminate a LOT the repeated

"_____
_____

Yahoo! Groups Links

---"
that kept filling up the message posts. We hopefully now know about the group, and where those posts orginate! ;)

And for some on-topic feedback..thanks for the link to that relay information. My 520 may be back up fully functional if I can replace that relay..its been too long that I have been off the HF airwaves.

73's to one and all...

John/N7QIV

Hi Bill,

There are 2 relays. One is under the small square box between the final board and the back side of the radio (next to the SG switch). The other is on the relay board just about in the middle of the layout. This one is not covered by a metal box.

I learned this from the group in the process of trying to fix my TS-820S. Still working on it.

Steve - K7QHU

6715. RE: [TS-520_820_530_830] TS 520 unstable meter

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-02-15 15:33:39 UTC
From: Hauser, Ron M.
Topic: 6705 Message: 6715

Hi Walt and Wayne. Wayne, I'm interested to know if you experience erroneous meter readings on other settings besides RF? Do you see it on received signal or drive level when tuning the drive? I have a very similary symptom on my 830, the meter does not move for low deflections. For received signals, I don't get deflection until about s6 signal strength. Signals are there, the receive sensitivity is ok, but no meter twitch. While tuning the drive with the CAR at low levels, I will see my external power meter twitch up, and not see the meter on the rig move. I then turn the CAR up and get a drive indication, which shows that I was near the peak.

I'm pretty sure I need to deOxit _something_, but I've been mulling over what. :) I'll try the RF Volt pot on back, and I'm planning to deOxit the calibration pots for the meter. I'll post my results, and Wayne, I'd appreciate if you would also as it may provide me some clues.

Thanks!

Subject: Re: [TS-520_820_530_830] TS 520 unstable meter

There is a adjustment pot on the side for this meter setting in the RF mode.
It is called the RF volt control. It is on page 13 of the manual. Clean this
control using De Oxit or rubbing alcohol.

You could also clean the multimeter switch. This is the switch that changes
the meter between ALC,IP,RF,HV.

Does it do this in the IP, or HV position or Just RF?

Place it in the center position to start with then adjust it for peak rf
output.

6718. RES: [TS-520_820_530_830] Initial position of LOAD control.

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-02-15 17:38:34 UTC
From: PY2FWA
Topic: 6716 Message: 6718

Ok Eric,

I did try to find some information on the manual, but I did not find
anything about this controls on initial tunning.

Thanks,

Alvaro

Place it in the center position to start with then adjust it for peak rf

output.
Eric

Tnx Alvaro,

Would you know off-hand how you would go about
removing and replacing the relay and where a
replacement might be found?

6722. RES: RES: [TS-520_820_530_830] TS-820 Relay Replacement - Hopefully Found one!

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-02-16 11:06:59 UTC
From: PY2FWA
Topic: 6709 Message: 6722

Hi Bill;

You need to loose 2 screws on that blindage(small square box) to have access to that relay.(you can see the photo in my album),first do try to clean the relay contact with deoxit(D5).. and after put some conservIt(P5).
This relay is very hard to find.

73
Alvaro

Ron,
I was getting the erronous readings in the RF position. The DeOxit
seems to have "done the trick". I work all CW and found it much more
reliable keeping the Meter Switch in IP position while transmitting.
This would be the true reading for your Plate Current.

Well, people may argue but the tuneup procedure that I prefer is to start with both drive and load turned fully CCW, which is the "minimum" setting on both (at least on my rig). I also preset the plate control to the position marked for the band.

I put the rig in TUNE, switch to send, and bring up the drive to peak. I like this because it brings the drive up from low to high.

Still in TUNE, still on Send, I switch the meter to IP and wiggle the plate knob to get a dip.

I then switch to CW, rig to send, and check the dip on the plate again. Then I start turning the load up. I have the benefit of an external power meter, so I don't have to switch the rig's multimeter. I bring up the load, watching the IP come up to the high limit while watching the power come up. On my 830 high limit for IP is 265ma, I think on the 820 it is 200ma. When I see the IP up to the high limit, I re-dip the plate control and bring up the load again.

After just a couple iterations (and only about 15 seconds) I am up to full power and near the max for IP. I feel that this method keeps me from running high IP during tuneup, and I feel good about that even if it probably doesn't hurt the rig for short times.

Your mileage may vary.

Subject: [TS-520_820_530_830] Initial position of LOAD control.

Hi Group:

My doubt is : Which is the initial position of control ""LOAD"" ?, Center, max ou minimum ? for initial tunning on the TS820S. DOnt have this information on the manual.

Yahoo! Groups Links

Hi Ron;

I always made tunning in accordance with the instruction manual. But the only doubts was which would be the best initial position of control load, in the manual does not have this information.
Thanks fer ur very fine information, great ..

Hi Bill,

Yes, you need to remove a couple of screws to get the metal cover off. This is one of those rare times that a magnetized screwdriver comes in handy. Make a note of which relay is which so you don't mix them up. GL,

This is an important point Jay made! I'm remembering back a bit but I believe that the original relays had the same part number but one contact was different and they had different coil resistances. So it is very important to mark the relays with something before removing them or you can get them mixed up.

Since these relay have same part number what is the difference between them ?
This would not cause confusion? Did you make some measurement on the coil resistences?

They are labeled with different coil resistances and one of them, I think it is the one in the rear has an oversized contact. Just mark them when you take them out and put them back in the way they came out. They will work reversed. But I get the feeling that it is better to have the one with the oversize contact in the original place.

It was a real crazy deal and there was no documentation on this. They have identical part #s I am not sure if this was the case in all production runs. I think that there may be a post in the files section of this group on this.

Hmmm the parts list calls them out different Ant Relay is a S51-4017-15 and the one on the relay board is a S51-4031-05 (this is the one Kenselectronics has the replacement for).

6731. Overcoupling an amp and the LOAD control....

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-02-18 01:41:19 UTC
From: ke9zm
Topic: 6716 Message: 6731

I had the same question about the LOAD control. There is no specific info on its initial setting in the kenwood uaers manual for the TS-520S. In this news group I have seen some folks say to start at full CCW and some say set it to center.

To go one step further, there is an excellent tuneup procedure for tube linears in general written by KK5DR. In this 4 page document he talks about "over-coupling" the amp by increasing the LOAD beyond max power out (reduces power out) to reduce grid current.

The link below is to KK5DRs tune up procedure for Linears. Was hoping some of the more knowledgable people in this group could comment and say how/if this applies to the Kenwood Hybrids.

6732. TS-820-S keying a Heathkit SB-200 Amp

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-02-18 02:12:56 UTC
From: Bill Richarz
Topic: 6732 Message: 6732

Will the TS-820-S key a Heathkit SB-200 amp or should
there be some sort of keying relay for it to go
through?

Bill,

Get the soft-key module for your SB-200 from www.harbachelectronics.com.
Been using it with my TS-530s and SB-200 combo for about 5 years with no
problems. It's cheap and does the job.

this information on the manual.
I always thought the Load Control was part of the pi network output settings.
So the setting would depend on the antenna, tuner, or dummy load you are
connected with to tune up.

Make yourself a tuning table and enter the knob positions per band centre.
That way you'll have the start positions for your station's antenna system impedances.
Cheers

Topic: 6716 Message: 6738

I've found the fastest and easiest way to tune up is to start with the load control at minimum, dip the plate current in the tune position then switch to CW and RF output on the meter. Key the rig while increasing output with load knob (toward maximum) then same with plate knob (usually toward minimum). Alternate between load and plate until you have maximum output. Keep key down time short.
Hope this helps.

Bill N4DH,
I agree with Steve. I've used both the soft-key and the soft turn-on modules from Harbach for several years, and they take all the stress off my SB-200 and the radio that drives it. They are not hard to install with normal handtools, and the instructions are good. I also use a soft-key module on my Collins 30L-1 amplifier.

6742. TS-820 With No Plate Current

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-02-21 06:53:44 UTC
From: Stephen Davis
Topic: 6742 Message: 6742

Hello All,

I am still troubleshooting my TS-820 with no Plate current as I get time and as I try to learn more about troubleshooting. I have a question. In the schematics for the TS-820, in several places they will show two values of voltage. For instance on the final board at pin 5 of the 6146b there are two voltages, one is -100 volts, and then in parenthesis under the -100 volts is -55 volts. Why two voltages for one point? I am guessing it has to do with the state of the radio, but cannot find anything to verify this.

Since the old e-mail with this topic was getting long, I started a new e-mail with the same title. Below is a summary of my problem:

When tuning the radio for transmit, I get no bias reading at all. If I switch the meter to the HF position, I do get reading of about 850v. Thanks to Walt, these are the things tried so far in troubleshooting the radio:

Voltage at the DRV test point on the final board measures negative 100 volts
Voltage at the SG test point on the final board measures 250 volts.
Built a voltage divider to safely measure plate voltage. The voltage was 270 volts (equivalent to about 810 volts on the plate).
Checked the cathode resistors (ok).
Checked Plate chokes for short (ok)
Checked relay on relay board (ok, or I should say contacts are clean and relay moves when I switch from rec to send)
Checked SG switch to be in the up (on) position.
Filaments light in all three tubes.
Substituted all three tubes, no change in symptoms.
Tried tuning on different bands, but no change.

Thanks

Steve K7QHU

From: Walt Breining
Topic: 6742 Message: 6746

Stephen:
I have saved the tricky part for last. Pins 5 are the control grid. While my diagram does not include voltages, I believe you will find that -100 V is receive and the -55 volts is transmit measured on SSB mike gain down.

The - 100 volts cuts the final tubes off during receive. The tubes have plate and screen voltages on them during receive but the - 100 volts on the control grid. As this voltage is raised toward zero volts, the tube will start conducting.

Measure the - DC volts on these pins with the rig in transmit,SSB, mike gain down, SG ON. It should change as you rotate the bias pot. Also check it at the FG (final grid) pin on the board..

The bias control controls Q5 on the RF board that in turn controls the FG voltage on transmit.

I will be away from the computer until the end of the week. I will have to get a better copy of the diagram as my PDF copy is not good around Q5.

Good luck and I'll look for your results the end of the week.

The plate voltage and current gives the INPUT power used by the finals. You need a wattmeter to measure the actual output power. An estimate would be output is around 50% to 60% of the input power.

There is no specific power level adjustment. For SSB use lower audio level. For CW you could detune the DRIVE control but that also effects the receive side.

I always encourage new Amateurs to get a small soldering iron and begin learning how to install phone plugs, mike plugs, speaker plugs, and PL-259s. This will prove useful to you as you adventure not only into the Ham Radio hobby but also while working with computer based equipment.

You can purchase a cord with a molded phone plug on one end and an RCA plug on the other. These are quite common and available at Radio Shack. You can then cut the RCA plug off the end opposite the phone plug, and skin the wires down. The wire will be coaxial, and there will be a center wire surrounded by a shield. Connect the center wire to the key terminal that goes to the fixed contact on the key and the shield to the other post.

6759. RE: [TS-520_820_530_830] TS-820 With No Plate Current

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-02-22 00:14:42 UTC
From: Stephen Davis
Topic: 6742 Message: 6759

Hi Dave,

You are correct, and my statement was not clear. I checked to see if the plate chokes were open, and they were not.

Yes, the screen grid voltage does change when I operate the SG switch. With the SG switch in the ON position, I measure positive 250 volts at the SG test point on the final board. With the SG switch in the OFF position, I measure negative 100 volts at the SG test point on the final board. So it seems that the SG switch is working, just not sure if the voltages are correct.

Thanks

Steve K7QHU

"Checked Plate chokes for short (ok)"
Did you mean 'checked plates choke for open circuit and found very low resistance (ok)' ?

Does the screen grid voltage change when operating the SG switch?

6760. RE: [TS-520_820_530_830] TS-820 With No Plate Current

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-02-22 01:26:34 UTC
From: Stephen Davis
Topic: 6742 Message: 6760

Hi Walt,

I know you will be away from the computer until the weekend, but wanted to send this while it was fresh in my head!

Okay, with the mode switch in LSB, Mic gain down (fully counterclockwise), SG switch on (up position) and the send/rcv switch set to send I get the following:

Bias control fully counterclockwise Pin 3 = +250volts Pin 5 = negative 105 volts FG test point = negative 105 volts.
Bias control fully clockwise Pin 3 = +250volts Pin 5 = Negative 90 volts FG test point = negative 90 volts.

So, rotating the bias control from fully counterclockwise to fully clockwise causes a change of about 15 volts.

My copy of the RF board schematic is also not very readable. I don't have the original service manual, just a copy. I will start checking QTH.COM and such to see if I can find someone selling the actual service manual and not a copy.

Thanks

Steve

Subject: Re: [TS-520_820_530_830] TS-820 With No Plate Current

Stephen:
I have saved the tricky part for last. Pins 5 are the control grid. While my diagram does not include voltages, I believe you will find that -100 V is receive and the -55 volts is transmit measured on SSB mike gain down.

The - 100 volts cuts the final tubes off during receive. The tubes have plate and screen voltages on them during receive but the - 100 volts on the control grid. As this voltage is raised toward zero volts, the tube will start conducting.

Measure the - DC volts on these pins with the rig in transmit,SSB, mike gain down, SG ON. It should change as you rotate the bias pot. Also check it at the FG (final grid) pin on the board..

The bias control controls Q5 on the RF board that in turn controls the FG voltage on transmit.

I will be away from the computer until the end of the week. I will have to get a better copy of the diagram as my PDF copy is not good around Q5.

Good luck and I'll look for your results the end of the week.

Walt, I agree with you about getting the soldering iron but, and I tell this to all the newcomers also, if you don't know how to solder, strip a wire and such, please, by all means, ask.
I learned how to wire and solder when I worked for Western Electric and I have been going on for almost 37 years now in the phone company and let me tell you I think I have seen just about every problem you can have. I have been doing repair for many years now and I have seen what problems can arise when the person before me, yes even me, makes a mistake when they strip a cable or doesn't clean a solder connection, or doesn't use the right tool to punch down a LAN connection, it can be frustrating to say the least.
So if anyone has questions please, please, please, ask, be it your "Elmer" or the local club. Just remember, none of us came out of the box, so to speak, knowing how to wire and solder, we all made our mistakes and learned from them, probably learned a few interesting words and phrases too.

hi frank,

in cw, the carrier control adjusts the
the signal.

in SSB, using drive can lower the output
but can cause distortion and that is not good.

The only way to lower your output power is to
use the alc circuit (this works with an amplifier).

http://groups.yahoo.com/group/TS-520_820_530_830/files/MODS/

look here and go to qrp mod.

very easy to make and the 9v lasts a long time.

this is good for the digital modes like sstv
or psk31.

I always encourage new Amateurs to get a small soldering iron and begin learning how to install phone plugs, mike plugs, speaker plugs, and PL-259s.
This will prove useful to you as you adventure not only into the Ham Radio
hobby but also while working with computer based equipment.

You can purchase a cord with a molded phone plug on one end and an RCA plug
on the other. These are quite common and available at Radio Shack. You can
then cut the RCA plug off the end opposite the phone plug, and skin the wires down. The wire will be coaxial, and there will be a center wire surrounded by a shield. Connect the center wire to the key terminal that goes to the fixed contact on the key and the shield to the other post.

So you don't get a shock if you touch the arm or base of the key. I believe
the keying voltage is about 65V.

Hi everyone!

I'm new to this group and have a few questions. First let me introduce myself. My name is Sue and my call sign is KZ9L. I have a Kenwood TS-830S and am interested in working 6 meters as well as HF. I noticed the "xverter" connection on the back of the rig. Is there a transverter which is an accessory for this radio? I saw one on ebay which was advertised as being for the 820S but would work with the 830S "with a few modifications". Does anyone know what sort of "modifications" are needed to make it work with an 830S?

If this topic has already been discussed then please excuse the post and just point me to the location where I can get more info.

Thanks in advance and 73.

It does not matter a lot. But the moving part is more exposed. This could cause RF issues and cause a shock hazard on older transmitters that keyed higher voltages.

One thing I have found with automatic antenna tuners is that many if not all have less range than good manual ones. The automatic tuners are good for correcting mismatches on antennas that are resonant on or near the band of operation but often will not tune random dipoles, random wires, loops and 80 meter dipoles say on 40 meters. You should research the range specifications and determine if the convenience of automatic operation or wide matching ability is more important to your specific needs.

Perhaps there are automatic tuners with wider matching ability.

Hi all:
Looking for a source brand name etc for a manual antenna tuner to go between my 520 and the random wire running from the house to the big ole cottonwood in the back yard. All I see in the ads are good for lots of KW and lots of $$$$ and are automatic. Something with meters to tell me where I am. I have a Dentron Jr. that I picked up during the CB craze and don't really trust it except on really low powers.

I'm a Palstar fan. I have the AT1500CV. The components are more beefy than my MFJ-969 which I arc'd at 50 watts while experimenting with my antenna. If your antenna presents a high SWR to the tuner, having components that can withstand the high voltages (even at low power levels) really gives some peace of mind.

I love roller inductor tuners.

Check eham.net and qth.com classifies. There are often high power tuners there. I think I saw a Ten Tec 238 this evening which I hear is a good tuner.

I just happen to have a Palstar AT1500CV for sale. Just over 1 year
old, looks and works like new. Great tuner. If interested, please
email to: (my_callsign) @ arrl . net. Asking $365 +shipping.

How much power are you running? Dentron gear was never intended for the pseudo CB market and I would be surprised if it would not work for normal transceiver output levels. The big Dentrons work great. Let me know the model number and I will see if I can find some information on it somewhere.

If you can find an old, old, old Murch UT-2000B tuner on eHam or eBay etc. you'll get a roller coil tuner that will handle full legal power, with meter, that will tune just about anything that's conductive for about the price of the 300W MFJ unit with switched coil. I did and its a great tuner.

6778. Main Relay in TS-820S

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-02-24 18:29:42 UTC
From: Bill Richarz
Topic: 6778 Message: 6778

Received a replacement for the main relay from Ken's
Electronics. Popped it into the radio and instantly
my problem cleared up. Relay looks almost like an
exact replacement for the OMRON relay.

Also Checked out the ant. relay by removing the metal
cover on it and it appears to be the same type relay
except the contacts appear to be a bit larger and coil
is rated at 300 ohms rather than the 380 ohm value on
the main relay. I didn't even remove the plastic
cover on it as it is working fine as it is.

I have one other problem with the radio and will list
it later and see if anyone can help me with it.
Thanks to all that pointed me to Ken's store.

tnx, & 73 de Bill, N4DH

When I key up, I get white noise on my computer speakers, on a desk about 6 feet away. Also, when I use my inkjet printer, I get a patterned feedback on the rig. I can 'hear' the printer on the radio!

Do I need shielding or will that cause RF problems with the 520? Any recommendations or comments on why this is happening?

(Computer and rig are on seperate circuits, both run on UPS and are grounded, seperately.)

Back before computers...there was an FCC Regulation called Part 15..... which held manufacturers to design and market products that would not cause RFI.....Deregulation of the FCC in the name of "free enterprise" has made "Part 15" history. It's a "tit for tat"... Modern electronics manufacturers make stuff that interfers with you and then they do not use good RF supression designs in their products...so your HF rig gets into their products..... It's the almighty $$$$. Ignore it...in time you'll get used to it....HI HI
Put .01 MFD caps across the voice coils of your speakers, ad .001 bypass caps across your audio input RCA jacks....Put ferrite chokes on your printer cables.....or buy shielded printer cables. That might be a start. OR buy a screen room and put all you consumer electronics, and computers in there..... (I am being a wise guy....) Sorry!
It's a disgusting problem we shouldn't have to put up with! If the manufacturers would put another $1.50 worth of parts in there products, and properly engineer them in the first place. This would not happen.......

RFI in the shack is a problem. Fist thing about seperate ground is a no-no. ALL equipment should be grounded to a common ground point. Don't daisy chain your grounds from one piece of gear to another.
See Polyphaser web site for info.
http://www.polyphaser.com/kommerce_products.aspx

Secondly, get a bunch of ferrite. Every cable that connects a peripheral to a computer or rig should have ferrite on it to choke RF on the outside of the cables. This should be done to external speaker cables on your rig too. Pass the cables though the ferrite core a few turns and that should do the trick.
No ferrite on your coax.

Third thing is to make sure that you are using good quality coax and your connectors are properly installed. Make sure that your tower/antenna is grounded to the same common ggrounding point and your equipment and house electric service.

I realize that this may be a lot of work but if you keep at it and add more and more protection over time you will have complete protection.

A properly grounded station hears better also. You would be surprised at how much static will go away by grounding. The protection to your PC for the RFI it is getting from the rig will also help eliminate RFI from the PC to the HF rig.

My plan this summer is to add 3 more ground rods to the tower. A station is always a work in progress.

Good luck.

W3IZ once said:

> ALL equipment should be grounded to a common ground point.

Okay, I'll get on that tonight. Do I need to run a ground from all my electronics in the shack (i.e. PC, TV, stereo, etc.)? Or does the household plug ground fine for those items?

> Secondly, get a bunch of ferrite.

Done. Well, almost. I just purchased a bunch of snap-on ferrite cores online. I'll get those installed ASAP. It seems my monitor already has a ferrite on the video cable. I always wondered what that fat part of the cable was. Thanks to you, now I know! Should other things (i.e. wireless router power cable) have the choke on it too?

> Third thing is to make sure that you are using good quality coax

I think I am. It's RG8X, 50 ft, with very little slack between the rig and the dipole.

> Make sure that your tower/antenna is grounded

Well, my antenna's hardly a work of wonder. It's a 80-40 meter single band dipole (MFJ-1779B), trimmed to 34ft on each side.

To my best research so far, that was the ideal size for 40 meter (does that make it a 1/2 wave for 80?) Anyway, it's... please hold the chuckles, strung along the wooden fence, horizontally, and about 5 ft off the ground. Probably would work better 5 INCHES off the ground, but we have dogs.

I won't get Africa with that setup (particularly since it's N to S!), but I'm just getting my feet wet for now. I wanted to learn more before I spend more. Even when that time comes, I really haven't come up with a better solution to the antenna issue. I only have about 100 feet of property on the long side and I have high limitations. Hmm... that light pole on the street sure is looking tempting!

But the antenna's NOT grounded. I didn't think I needed to ground it, since it's not touching anything metal, but it does make sense that it should be. Would that be a plastic-clad wire running to the ground rod outside? If so, where on the dipole would I attach the other end? Anywhere along it? That seems like something I should know already, but I'm still learning what works with what I have.

> I realize that this may be a lot of work

Not at all, it's a pleasure to learn. The only drawback going from tech to general privileges has been the immediate drain on my bank accounts! I'm sure that's a burden many of us can appreciate.

> Good luck.

Thank you and thanks to all those that have (and might again) help me and other 'noobs'.

Topic: 6772 Message: 6785

For 25 years I used one of those 300 watt MFJ tuners with the built in dummy load, switchable inductor , and two capacitors for tuning. It has worked ok over the years. Recently I aquired a Palstar AT1KM. Tunes well and is built well. The insides of my ole MFJ are built just enough to get the job done. The Palstar is more than that. However, it does not have a built-in dummy load like the MFJ. There is a switch position provided on the front panel that bypasses the tuner to a connector on the back where I have my external dummy load connected.

Kay:

I have never heard of an R820 receiver. That sounds like it would be a real nice addition to a shack. Was the R820 the end of a line or is there a follow-on R830? Is the 820 a general coverage or ham-band receiver?

Hello Kevin,

the R 820 was the end of the TS820 line.
It was not general coverage, it was a classic
hamband receiver with a converter for some
radio bands.But it was build very professional,
with switchable crystalfilters independend from
the modulation.It was only manufactured for one year from 1977 to 1978.I do
add some fotos from inside
of the receiver on my website.

6791. TS820: In rig meter checks out (K0ZL)okay ip, HV, but power out down..suddenly

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-02-26 20:34:12 UTC
From: Roberto Baca Barnard
Topic: 6791 Message: 6791

Hello Group fm WB7AVF/2:
I'm new and have read the files section and many of the messages. Here's the situation: One TS820, operating since September cleanly and efficiently, CW only, at 100w (or less) through MFJ 949E "tuner" into coax-fed, 40m dipole, 20 ft feedline, 100 feet above ground. Clean, dust-free, treated gingerly. Given rig in September by friend who mentioned that "tubes might be getting old" but rarely ran it.

Always followed manual tuneup procedures. i.p idle always at 58ma and very careful to not push the old rig too hard. Don't have test equpiment in my apartment QTH save for a volt/ohmmeter.

PROBLEM: Won't load up properly, power down, spongey. Suddenly happened day before yesterday...

Noticed that rig was not loading up properly after 20-50w all bands, becoming spongey and CAR control ineffective; REflected pwr meter on MFJ high reading, even on dummy load. This had never occured before; crosshairs always well in check; now Reflected PWR needle hard to the left. Checked mechanical connex of course to start with, SG sw, etc. First thought: something funky with the transmatch, say, dummy load Resistor bad or dirty contacts. It reads 41.8 ohms and is well connected. Mechanically MFJ looks okay...Though I'd like to know if they can give trouble.

Followed "in rig" tube check out procedure as outlined by K0ZL. STATS: I.P. FINE H.V. FINE. No decays or abrupt changes under any of the tests outlined. ONLY THING VARIED IS THAT turning up bias pot as suggested in part of the test gave 190ma, not "well over 200" as he said. But there was no decay, sudden drop off, etc. In other words, maybe elderly tubes, but not dead (?)

Tried again. Same thing. Rig doesn't seem to "load up" into dummy load or antenna for full output. Turning up carrier level pots up above 200 if wanted but SWR meter refected pwr very high.

What's up? I have to go QRT anyway while moving this week
SO NOWS the time to check it out and fix it as best I can as an evening project. I will miss
my TS820 as it's my
only non QRP rig and had plans to give it a new ladder line fed antenna.

6792. Kenwood TS-830S with receive problem

From: trwinok
Topic: 6792 Message: 6792

Hi Group!
I have a TS-830S that has developed a recent problem. One morning when it was turned on I noticed the receive sensitivity was down. It still receives, just not as well. After playing with it a bit I noticed the meter was no longer moving at all and the gain control had no affect on the received signal. I've already tried replacing the TX/RX relay to see if that helped, but it made no difference. Does anyone have any suggestions on where to start looking for this problem or has anyone ever seen this problem before?
Many Thanks for your help!

My first guess is that there is nothing wrong with the rig. It is something after the rig. Is the dummy load separate from the meter? If so:

1. Check the resistance of the dummy load with an ohm meter. It should read close to 50 ohms.
2. Connect a coax jumper to the dummy load and check the resistance at the end opposite the dummy load. It should read the same.
3. If the above checks out, plug this jumper that is connected to the dummy load directly to the TS 820 and see if the spongy effect goes away and things act normal.
4. Is so obtain another watt meter of good quality. Connect the dummy load to this meter and connect a jumper to go from the meter to the TS-820. Before plugging it into the rig, check the resistance across the plug that you are going to connect to the TS 820. It should still be around 50 ohms.
5. Now connect this combination and load up the TS 820. If everything is OK start substituting things until the problem reappears. Find the bad items by the process of elimination.

If the rig still acts defective with the dummy load connected directly, how much ALC do you get with the carrier fully up and the drive control peaked for maximum ALC on CW ? Is it normal?
If not, I would suspect the 12BY7.

If none of the above reveals anything, you need to check out the screen voltage and look for a defective fixed capacitor in the PA area.

I am betting that it is not your rig.

Hi Walt and thanks for the procedure. The MFJ dummy
load is a cigar shaped resistor with a metallic
coating of some sort on each end. It's removable from
its mount (snap in). Tests 42 ohms, removed. Will
follow up on this.
--- Walt Breining <n9wb@...> escribi?:

My first guess is that there is nothing wrong with the
rig. It is something
after the rig. Is the dummy load separate from the
meter? If so:

1. Check the resistance of the dummy load with an ohm
meter. It should read
close to 50 ohms.
2. Connect a coax jumper to the dummy load and check
the resistance at the
end opposite the dummy load. It should read the same.
3. If the above checks out, plug this jumper that is
connected to the dummy
load directly to the TS 820 and see if the spongy
effect goes away and
things act normal.
4. Is so obtain another watt meter of good quality.
Connect the dummy load
to this meter and connect a jumper to go from the
meter to the TS-820.
Before plugging it into the rig, check the resistance
across the plug that
you are going to connect to the TS 820. It should
still be around 50 ohms.
5. Now connect this combination and load up the TS
820. If everything is OK
start substituting things until the problem reappears.
Find the bad items by
the process of elimination.

If the rig still acts defective with the dummy load
connected directly, how
much ALC do you get with the carrier fully up and the
drive control peaked
for maximum ALC on CW ? Is it normal?
If not, I would suspect the 12BY7.

If none of the above reveals anything, you need to
check out the screen

I'd have to recommend against MFJ right now. I bought a shiny (allegedly) new MFJ auto tuner on Friday. I took it home, opened the factory sealed box, and took out a banged up tuner that appeared to have been inexpertly repaired. I immediately returned it. The dealer (who bent over backwards through all of this to make things right) brought out the only other one of that model in stock. We opened it right there and found a small ding in the front of the case. Neither of us noticed the odd way the meter was mounted. I decided to take it home and try it since I had the dealers assurance of a full refund it it wasn't right. It wasn't. I got wildly varying readings when I keyed up the radio. Sometimes it reported a match, sometimes it reported that it couldn't find a match, sometimes nothing happened, and sometimes it locked up, displayed "powerdown", and had to be reset before anything worked. I'm still looking for a tuner, and I'll be checking out the companies recommended here. I do, however, know which company I'll avoid in the future.

Hi to ALL

I'm own a TS-830S & a TS-930S. Now I'm looking for some more OLD-Kenwood stuff:

- TS-520S / 520SE
- VFO-520
- DFC-230 or some other digital readout
- VFO-230

Is anybody here to sell this Parts? All have to be in excellent shape. Please let me know.

Daniel, HB9DDS

6799. Looking for some great Kenwood stuff ## 2

Topic: 6799 Message: 6799

I will made a correction to my previous posting:

Now I'm looking for some more OLD-Kenwood stuff:

TS-520 Stuff:

- TS-520S / 520SE
- DG-5 (external Digital Display)
- VFO-520S (external VFO)

For my TS-830S:

- DFC-230 (Digital Frequency Controller)
- VFO-230

Is anybody here to sell this Parts? All have to be in excellent shape. Please let me know.

Daniel, HB9DDS

6800. TS-520SE tuning indents (flat spots)

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-02-27 21:37:30 UTC
From: Jim Adams
Topic: 6800 Message: 6800

Hi everyone. I am a new member to the group. I have had my General for about 4 months. I was a novice for a year in 1954 so it's been awhile. My rig is an old but loved TS-520SE which has developed indents (feels like a flat ball bearing) when rotating the tuning knob. Has this been discussed before and can anyone help identify the cause and possible fix? It still tunes OK, but I have noticed that if on a 'flat spot' the dial will drift to either side. Thanks for your help.

6801. TS-820S Display Problem Resolved

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-02-27 22:14:27 UTC
From: wb4ouf
Topic: 6801 Message: 6801

Hi All,
Back during the first week of Feb., I posted a query regarding the ongoing display problem I had been having with my 820S. Since then I have done absolutely everything known, suggested and invented to try and resolve it. Today, I decided to "get on it" again. I decided to make a few more continuity checks before I disassembled everything for about the 6th time. The first thing was to re-check the filament continuity of the display tube. I disconnected the display from the DG1 and when I went to place the probes on the "p and f" connectors (filament supply lines), I noticed that the "f" connector looked different than all the others. I decided to remove the connector pin from the main "block" and when I depressed the retaining leaf, I noticed absolutely no resistance. I went ahead and removed the pin and the leaf dropped out with it. The leaf had broken off the pin. I went ahead and re-connected everything and "hard wired" pin "f" and ..... IT'S ALIVE!! Evidently the leaf being broken provided no pressure for the connector to make good contact with the pin and everytime I made voltage and/or continuity checks, the meter or scope probes provided enough pressure to make the connection. With my eyes "glued" to the meter or scope tube I never "saw" if the display came on or not....Hi! Anyway, I just wanted to make sure that I told as many people as I could... I know what the "fight" is like!
So...If you have 820S display problems, do everything you ever heard or read and make sure you "CHECK EVERY CONNECTING PIN FOR THE POSSIBILITY OF A BROKEN RETAINING LEAF"...

Best 73's
Frank WB4OUF

PS: Anyone know a source for those wire end connectors?

6802. regarding my newly purchased ts-830s

I am new to ham radio and not much of an expert in all of this. The radio has all filters in it but one of them is facing the other way. Can read three labels from the front but the fourth faces to the back. Is that normal or is it significant of anything bad. Also the coax connector is solid on the back but is not perpendicular to the back wall plate. Its cocked about three to five degrees to the left as I stand in the front. The fan housing is flush on three sides but the metal plate is slightly pushed in under it exposing about an eighth of an inch of space which seems to have caused the cocked coax connector. As I have several daays to return the radio, do these things seem worthy of returning the rig. It does work. I made some contacts. Too new to tell if its working at its best. Cosmetically, should they have sold it to me that way. Would appreciate any comments that could ease my worries or let me know to send it back if need be. Thanks for any help you can give.
Sincerely, Tom kb1mak

From: Ken Winterling
Topic: 6802 Message: 6805

Tom,

The filters can be installed either way, they are not keyed nor polarized. It just looks better if they are all installed the same way. I wouldn't remove a filter just to reorient it.

The mechanical issues you describe with the coax connector and fan are not normal and are indicative of an impact. The rig may have fallen and landed on the rear. Check the insulator of the coax connector for broken pieces. Was the rig shipped to you? This could be shipping damage. Check the carton for damage. Was there adequate packaging to prevent the rig from moving in the carton?

Good luck.

Ken, WA2LBI

Frank:

Can't help with the connector but I really appreciate all the troubleshooting and progress posts you made in resolving the problem. One thing I've learned from them, with these old rigs, look as hard at the mechanics as the electronics when troubleshooting.

73 and congrats on the repair,
Kev - K4VD

From: lajes67
Topic: 6792 Message: 6807

I've got a 530S that had almost the same problem, one day it worked next day nothing on the receive but the strongest signals could get the meter to even move. I checked and cleaned both relays but that didn't change anything. Someone mentioned K4EEA and I found his web site and spoke with him. I sent the rig off to him and he did find the problem, he said he found the problem in L41 which had a short and there was another item but I cannot find the email that said exactly what it was. Perhaps you can give him a call and he can tell you exactly what he replaced. The only work bench I have is a small part of a desk and just the basics for tools, it was worth the cost to send it out for repair. After he did the repair he cleaned it, lubed the parts that needed it and tuned the rig to specs. I am very happy with the results.

Hi all from VK.

There's a mob here called Emtronics (same people that make the Emtron DX-2/DX-3 and DX-4 amplifiers) that use to make a very nice little 300w ATU called an EAT300. I have owned several, having always regretted selling one only to have to buy another when some other so called better ATU would not match my wet piece of string.

I now have their EAT1000A which will match a damp string easily from 160 to 6m... it will tune my G5RV on 6 and able to work DX. Not sure if the 300a is still made but I saw the eat1000a at a field day a few weeks back and can not see any ATUs on their web site at http://www.emtron.com.au/ but might be worth an email to check out US$ price???

With the exchange rate, might be worth looking at a quality made Australian ATU.

Cheers.
Pete.

A word of advice about using antenna matching networks to obtain a good SWR reading; A good SWR is not an indicator of an efficient antenna. Think of a dummy load, perfect SWR but lousy radiator.

The tuner or matching network as it is properly known, is designed to efficently transfer power to the antenna or in other words couple the transmitter to the radiator. Think of like the transmission in your car. While it is possible to connect the engine directly to the wheels it would not be the most efficient or effective way to tranfer the power from the engine to the drive wheels.

When tuning short antennas on frequencies like 80m or 160m it is possible that you could be converting much of the RF energy into heat energy.

When all possible cut a resonant antenna for the band that you wish to operate. Suprisingly this will yield more contacts and eliminate a lot of RFI issues that we read about on these reflectors.

In a message dated 2/21/2006 4:34:10 P.M. Pacific Standard Time,
TS-520_820_530_830@yahoogroups.com writes:

is there a cw straight-key that i can get without having to make one
for this rig? any recommendations?
I use a brass key that I purchased years ago at a war surplus store. No
markings on it at all, but looks just like the one I used in the army along about
1943 or 1944.
Well maybe there is some markings, but I bolted the key to a sardine can
that I filled with lead. That keeps the sucker from sliding around on the table.
So I am sure you could find a key maybe with one of those code practice
oscillators that are sold various places. My key has old type binding posts (and
a shorting bar) and I just used lamp cord to solder on a plug that fits the
socket on the back of the 520.
Also a key is not too difficult to make, that was one of the projects in my
Jr. High electric shop class.
Now all I have to do is learn to use a key again, Hi hi.

Seems like the "K-4 Chinese Military Straight Key" is a good choice.

Reviews are high and it's priced low. Nicely weighted (over 2lbs) and has the connection plug ready-installed (at least for the 520, I don't know about other models, but imagine it's similar.)

Check it out on eBay, eHam.net and, of course, Google.

I think the filters can go in either way. As far as the dent is concerned, the fact that you are concerned about it would tend to make me think you should send it back, especially if you are not confident that the rig is working properly.

I personally would keep the radio if I got it at a decent price and it worked as it should, but as I say, if it bothers you enough to ask the question, you probably should get your refund.

I have a TS-820 and have had problems with the meter being intermittant on receive and on drive peaking and ALC monitoring. I thought it was a fault on the IF board but now think it is an intermittancy in the relay board somewhere.
If I need to replace the relay, can anyone tell me where I can get hold of a 385 ohm OMRON MH4P relay. I live in the UK.
I look forward to a reply

6821. Re: [TS-520_820_530_830] MH4P omron relay

I bought a replacement from Ken's Electronic Parts.
http://www.kenselectronics.com

Ph. No. (269) 345-4609

The price was $18.00 US.

New relay fixed my problem of S meter hanging up when
going from xmit to receive and making a sucking sound
which was very irritable. Just tell him you need the
main relay with 385 ohms.

Good luck,
73 de Bill, N4DH

TS 820
While you are in there VR4 on the AF AVR board is known to become intermittent. Touch it with a plastic tool and see if the rig goes crazy. Is so it will need replacing and resetting..

Hello Walt and group:

You say driver tube next suspect? Will have to buy one then. Why?

Borrowed a Fluke meter from local TV repair guy and tested my MFJ tuner; thought perhaps diode or two, R near TX input toroid might be shorted per MFJ tech's on-phone advice. Nope. Looks okay. Mechanically sound and the Dummy Load resistor tests at 43 ohms--within tolerance.

Re ALC on full CAR out: over 275 pushing 300ma into "tuned" dummy load but 50w r.f. output max.

Opened up TS820 preliminarily to see where driver tube can is; yup--right on top. Took off fan on back to peer in at Finals area. The tubes have brown bases and what appears to be Japanese written on 'em.

Please more advice...will cough up for 12BY DRIVER TUBE from surplus sales if sound store. Here in NYC there's a place called Leed's Electronics out in Brooklyn (been around since Hiram Percy Maxim was still W1AW I think) but mail order tubes might be best?

tnx much

6825. Question re: use of 6146A tubes in 830S

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-03-01 00:03:26 UTC
From: Sue Kent
Topic: 6825 Message: 6825

Hi everyone!

I'm new to this group and recently purchased an 830S on eBay. While installing the CW filters and doing a routine check, I noticed that the finals are 6146A's instead of 6146B's. I'm concerned that the rig has been damaged by the previous owner's use of the wrong tubes. It seems to transmit and receive fine but I've only transmitted on it once from a friend's house (I don't have an antenna yet). The power out was about 80-90 Watts. Should I replace the tubes? If so, is it OK to use the 6146W series or is that subject to debate as well? Help!!

Thanks in advance,
Sue KZ9L

hi wally,

the vfo conector is 9 pin miniature on top,
not the larger 8 pin accessory connector.

the cable is 1-1 straight connect,
pin 7 is not used.

the male plugs are available from
kenwoodparts.com, part numbers in the
database section of this group.

Hi Sue.
The 6146A tubes are just fine.

Please check out the info on the 6146 family of tubes.
http://home.comcast.net/~zcomco/The_6146_Family_of_Tubes_1.htm

Your tubes may be soft if only 90 watts across the bands. I would give the rig a complete cleaning of all controls with de-oxit and check the usual meter readings -bias, IP, HV, etc to make sure all is well befor digging into the rig.

6146A tubes shouldn't hurt your rig. What band was it 80 to 90 watts? Was that tuned for max on 40 meters with the carrier control fully up? Are you sure that your watt meter is reading correctly?
Was this into a dummy load? If not what SWR?

I doubt if there is anything wrong. Enjoy the rig.

Tom. let me echo Ken's suggestion.

Several years ago, I wanted to get back into HF, and I bought a used Kenwood pair (R & T 599D) from a commercial dealer at a hamfest. I loved the radios, but I discovered that when I tried to tune the transmitter up on the higher bands, it would not tune. So, I ended up shipping the transmitter back to the dealer for repair. He fixed it and shipped it back via UPS.

When I got it back, the rig had obviously been dropped on its back panel during shipment. The fan housing was pushed into the back of the rig, and the bottom was warped so that it did not sit level. The packing appeared to be good, but it had really been mishandled. The dealer was a real pro about it. He had insured the radio for the return and immediately sent me a refund. He did the hassle work of collecting from UPS. I saw the dealer at another hamfest a short time later, and he told me that he finally got his money from them.

Shippers don't seem to like electronics all that much.

Oh, and I used the refund to get my 520. :)

Tom,

The mechanical issues you describe with the coax connector and fan are
not normal and are indicative of an impact. The rig may have fallen
and landed on the rear. Check the insulator of the coax connector for
broken pieces. Was the rig shipped to you? This could be shipping
damage. Check the carton for damage. Was there adequate packaging
to prevent the rig from moving in the carton?

Good luck.

Does anyone happen to have a "fried" AT-200 with a good "R" tuning capacitor they might want to part with. If not, possibly someone could lead me in the right direction. I have tried the East and West sources and, the part I need is not available. The insulated shaft on mine is "busted" beyond repair. Thanks es 73's

I own TS-830S and it's not in best condition. Does anyone knows the specifications of the RF-coils at
the front-end of the transceiver? On my radio, few have a cracked slugs and replacing entirely the coils might be a better solution. On 10.1MHz the radio is almost "deaf". Thanks in advance!!! LZ5ZM, Kalo.

Nine times out of ten it's the drivers.

I recall a big box of assorted 'pooter gear[s/h] we had delivered at
work a whileback.
It had been very well packed, and suitably labelled [like how big do
you want the word 'fragile' to be ?]

It came off the wagon upside down, and did not survive the 3 foot drop
onto the road.

I think the important thing when receiving goods like this, if they look like they've been dropped and the packaging is obviously damaged, don't sign for it. You have a much stronger case when you claim for it then. When you sign for it you're basically agreeing that you received the item in good condition.

Not to get off the track here from the original thread but the most common problem with the Twins not working the higher bands on transmit is the deterioration on over time of the pre-driver transistor, 3SK22. It drives the 12BY7, sits nearby it, and is the only one that has a transistor socket. It's easy why Kenwood used a socket here. Lots of heat from the 12BY7 kills the high frequency response of the transistor making it useless on the higher bands over time.

As mentioned I get over 280 ALC reading (drive peaked optimally as well) but RF output 40-50 watts max and then SWR reflected goes up fast and CAR control spongey, ineffective. Don't have wattmeter unfortunetely $.

If it's indeed outside of rig then can ONLY be MFJ transmatch. Antenna (dipole) is mechanically sound (checked it, double checked). It's made with one of those TenTec ladder/coax grippers and connection solid.

tnx Walt for your assistance when you have a chance.

6837. Is it me or my TS-520

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-03-02 06:25:06 UTC
From: wohtex
Topic: 6837 Message: 6837

Hello to the group. I have a TS-520 that is teaching me troubleshooting techniques for the electronicaly challenged. I posted last Sept with ALC problems on tune up and found I had a bad 12BY7A which I replaced and it seemed to solve my problems. I also discovered at that time the final tubes were mismatched a 6146A & 6146B (this is an ex-radio club radio purchased off e-bay) anyway I set the 520 aside and have been playing qrp with another radio. I also have the TV-502S 2 meter transverter that I had not been able to get working, so last week I went back to checking it and found the cable between the 520 output to transverter input had a broken center connection, once repaired I got the 520 back out and found it would only provide enough drive to the TV-502S for about 2 watts out so tonight I checked out the TS-520 again on each band and here is what I get. First on transmit I measure 850 volts HV and when checking the IP I can run it up to 250ma which will hold steady. all tune ups were done on a dummy load and external watt meter. I also had a Yaesu FT-77 sitting on the desk with antenna disconnected. Initial IP checks on all bands was 60ma. using the tune up directions in the manual here is what I get.

1. 28.300 MHZ, No ALC with carrier control up to 10 and drive to max.,on changing to IP no reading and plate control wouldn't produce any activity, meter to RF load control would go to 20ma scale, on cw RF reading would stay the same no further tuning would produce more, IP would read 130ma watt meter 40 watts, S meter on FT-77 10 over 9.
2. 21.300 MHZ, ALC to 70ma with carrier control on 10, go to IP reads 20ma and no plate dip, go to RF and meter max right readjusted for 2/3 scale, on cw RF tuned to 70 watts out and IP of 240ma, FT-77 showing 10 over 9.
3. 14.300 MHZ, ALC at 120ma with carrier control on 10 (noted that sometimes drive control would not produce anything and on retry all at once at a sharp point it would produce ALC reading with a sudden meter jump) turned to IP and plate would dip about 5ma, turned to RF and load control wold not increase reading, turned to cw RF and could tune 200ma scale and 100 watts out with IP at 200ma FT-77 20 over 9.
4. 7.300 MHZ, ALC 150ma scale with carrier control to 10, go to IP and plate will dip 10ma, go to RF reading 40ma scale and load control will not increase reading, changed to cw RF and load & plate will produce a reading of 50ma scale, watt meter reads 100 watts Ip will check at 220ma.
5. 3.900 MHZ, ALC zero, change to IP 30ma with no plate dip, changed to RF no reading and load control would not produce anything, changed to cw RF reads at 60ma scale no change with load and plate adjustment, watt meter shows 70 watts out, IP checked at 200ma, FT77 shows 10 over 9.
With a MC-50 mic and mic gain set between 8 & 9 I would get about 3/4 scale on alc meter on voice peaks.

I am concerned about areas that don't show a meter reading and I don't know if its my mistuning or what. Have a new set of final tubes but don't want to put them in and damage them. Have considered that problem may be due to RF Section Alignment or Drive Coil Alignment or possibley these final tubes just stuck in the rig to sell it and never neutralized.
O.K. after reading all of this you guys take a break then come back and share your expertise on these great radio's. If I can get this rig operating right I'll have the confidence to chage the band switch coupling on my TS-830 parts on hand just building up nerve. Got to learn someway.

thanks to everyone that took the time to read all of this.

Hi group and folks who answered my question,

I thank you greatly for your helpful comments about my rig. I just went and looked at the back again with even a magnifier. The fan housing looks mint and doesnt appear to have taken the load that would be needed to deflect the metal back under it and the coax connector about 1/8 inch inward. Also, the coax connector is very solid with no play . I now would have to think that an impact load newly done would have left it a bit wiggily. I can only hope that the seller / repairman had inspected it as he told me before I bought it that he went over it completely and alligned, lubed and checked all functions on all modes. He also said the tubes were right up there and the set looked like it had low time. Perhaps he fixed it if it was wiggely or loose. Also the box came in to me from fedex in a very good shape. He has given me time to check it out and send it back for repair or refund if I feel its needed. I truly love the rig and it suits me just fine. I dont really want to spend another 800 dollars to get one of thse menu driven complex new radios. Thanks again. This is a great group and I am very happy to be a member of it.
sincerely, Tom kb1mak

Go to Ace Hardware. Get a rubber light bulb socket like is used for
temporary lights in construction sites. Place a 100 watt light bulb in the
socket. Hook it directly to your Kenwood via a PL 259. Tune up the Kenwood
into it. Does it glow bright ? If so, your problem is outside your rig.

Hi Roberto. I read your previous message and you said your MFJ tuner checked out ok. However, I must tell you I experienced similar symptoms; spent much time fretting about radio problems, and found that the forward power diode was out of my MFJ tuner. From my research at that time, I found out that many people have the diodes go out of these tuners, it is a common problem. Two new 25 cent diodes, soldered in on top of the old leads, fixed my problem. In my case the forward power diode was completely dead, it would barely read a few watts when the radio was on full power. In your case, I wonder if your forward power diode is "half-dead" which might allow it to test ok with a fluke, but not give valid readings on SWR when you run up over 50 watts.

If I were you I would look long and hard to find someone who has a wattmeter you can borrow for a few minutes to verify that the problem is or is not the radio. In the abscense of a wattmeter to prove the location of the problem, I would go over that MFJ tuner with a fine toothed comb, and even if you can't find a failure in the diodes, it is probably easy to replace them. On mine, the diodes were on top of the main board, which is hard to remove, but I just snipped the diode out leaving the leads on top of the board and soldered the replacements to the old leads. Five minutes of soldering and it has worked like a champ since then.

Good Luck!

Hey Ron:
You know, to be honest--I got that suspicion too, regardless of the Fluke test which was done on the fly. The clip and solder idea sounds like a winner, especially cause it's fast. LOGIC tells me you're on to something; the ODD meter readings plus over-the-phone MFJ tech Janet's mention of the diodes initially had me onto that.

I'm gonna do Walt's lightbulb test (what's a 100 watt bulb HI HI) AND resolder piggy-back a couple germanium diodes I'll raid from an old t.v. set. I know a wattmeter's in order; must get for future work anyhow.

Won't bug you fellas til I do these things. By the way, this TS820 was well cared for by its previous owner in Seattle area. Very nice condition. It's barebones model; no CW filter, no 820S digital readout (fine by me), no XTALS. The owner did install the mobile power converter I see.

anyway, tnx much and

73
--- "Hauser, Ron M." <eichmann@...> escribi?:

Hi Roberto. I read your previous message and you said your MFJ tuner
checked out ok. However, I must tell you I experienced similar
symptoms; spent much time fretting about radio problems, and found that
the forward power diode was out of my MFJ tuner. From my research at
that time, I found out that many people have the diodes go out of these
tuners, it is a common problem. Two new 25 cent diodes, soldered in on
top of the old leads, fixed my problem. In my case the forward power
diode was completely dead, it would barely read a few watts when the
radio was on full power. In your case, I wonder if your forward power

diode is "half-dead" which might allow it to test ok
with a fluke, but
not give valid readings on SWR when you run up over 50
watts.

If I were you I would look long and hard to find
someone who has a
wattmeter you can borrow for a few minutes to verify
that the problem is
or is not the radio. In the abscense of a wattmeter
to prove the
location of the problem, I would go over that MFJ
tuner with a fine
toothed comb, and even if you can't find a failure in
the diodes, it is
probably easy to replace them. On mine, the diodes
were on top of the
main board, which is hard to remove, but I just
snipped the diode out
leaving the leads on top of the board and soldered the
replacements to
the old leads. Five minutes of soldering and it has
worked like a champ
since then.

Good Luck!

73

POWER OUTPUT DOWN

As mentioned I get over 280 ALC reading (drive peaked
optimally as well)
but RF output 40-50 watts max and then SWR reflected
goes up fast and
CAR control spongey, ineffective. Don't have wattmeter
unfortunetely $.

If it's indeed outside of rig then can ONLY be MFJ
transmatch. Antenna
(dipole) is mechanically sound (checked it, double
checked). It's made

with one of those TenTec ladder/coax grippers and
connection solid.

tnx Walt for your assistance when you have a chance.

73,

RBB WB7AVF

A word of advice about using antenna matching networks to obtain a good SWR reading; A good SWR is not an indicator of an efficient antenna. Think of a dummy load, perfect SWR but lousy radiator.

The tuner or matching network as it is properly known, is designed to efficently transfer power to the antenna or in other words couple the transmitter to the radiator. Think of like the transmission in your car. While it is possible to connect the engine directly to the wheels it would not be the most efficient or effective way to tranfer the power from the engine to the drive wheels.

When tuning short antennas on frequencies like 80m or 160m it is possible that you could be converting much of the RF energy into heat energy.

When all possible cut a resonant antenna for the band that you wish to operate. Suprisingly this will yield more contacts and eliminate a lot of RFI issues that we read about on these reflectors.

this winter in vk
using a vertical hf6v miss matched with a ft7 with 10 watts into a
home brew Trans matcher from vk6 western Australia contact was
obtained right up to LA north east coast of Norway working qrp
with Trans match removed no signal heard
and also worked into Russia with the same set up
I agree about getting your antenna as close as possible (cut and match)
some of us have less than perfect situations
why use a gear box in a vehicle (to enable the vehicle to encounter
different situations) like hills and to take of from a standing start
easily
a.t.u. does a similar job
use an atu it will help that small miss match nothing wrong with a
little help

6848. Re: [TS-520_820_530_830] Manual antenna tuners

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-03-03 10:56:30 UTC
From: Walt Breining
Topic: 6772 Message: 6848

While this is very true, an antenna system does not have to have a good SWR or be resonant to be efficient. A good general rule of thumb is that any system fed with coax needs to be resonant and provide a good match to the coax at the feed-point.

If an antenna that once had a good SWR or is supposed to have a good SWR develops a high SWR, it is an indication of a malfunction and cannot simply be fixed with a tuner. The physical problem has to be addressed

Antennas fed with good quality balanced line do not have to be resonant or have a match to the line at the feed-point. When fed with balanced line, if the antenna is at least 1/8 wave on each side, half of a 1/2 wave dipole, the efficiency will be a bit down, but not all that bad.

When high SWR causes loss, it usually occurs in coaxial line. This is assuming that the design and connections are of good integrity and the radiating portion is made of a good conductor.

A 80 meter dipole is not going to be efficient on 40 or 160 meters even if the tuner will tune it, if it is fed with coax.

If fed with balanced line, this same antenna will be very efficient on all H.F. frequencies above 3.5 MHz and only slightly reduced in efficiency on 160 meters. Unfortunately, most automatic tuners do not have the range to tune such an antenna, but most good manual ones do.

If a tuner will not except balanced line, a balun can be placed at the back of the tuner and connected to the coax input with a short coax jumper. I have had just as good of success using 1:1 baluns as I have using 4:1 baluns this way.

Of course, the above described antenna would be SLIGHTLY better on 160 meters if it was a half wave or longer on 160, and would be about the same efficiency on the frequencies above 160.

So if the SWR is high, and you are using coax, and the coax is more than 10 ft. or so long, you are going to have high loss. If you are using quality balanced line, you should not have high loss provided the antenna is at least half of the overall length of a half wave dipole. The shortening will cause a slight reduction in efficiency but you would be surprised at how little this is even when reduced to 1/2 the required length for a 1/2 wave dipole.

It is interesting what you find out when you run this stuff on EZ-NEC.

Now one more thing:

The reason Coax is lossier at high SWR is that on any feed-line, SWR multiplies the flat line losses more and more as the SWR increases. Compared to balanced line, even very good coax has much greater loss when flat than balanced line when flat. Even though the flat losses on coax are greater, when operated flat they are still so low so as to be of little problem. But when multiplied these coax losses become significant. Since the flat losses of balanced line is so low, it does not amount to nearly as much when multiplied due to a high SWR.

A very low number when multiplied by a number is less than a higher number multiplied by the same number.

Feed-line loss is a function of length. So a short coax with a high SWR will have less multiplied loss than a long one.

I hope that this is all about an antenna for a Kenwood or I am off topic.

There is a good Yahoo Group ham-antennas@yahoogroups.com where we discuss things like this all the time.

For the TS 830.

Pin 1 Yellow audio wire surrounded by the shield.
Pin 2 Vilot wire for PTT
Pin 3 Red Wire PTT Ground
Pin 4 Shield wire.

Be sure that the shield wire does not touch the shell of the plug. I surround it with tubing If it touches the shell, even though it is ground, it will create a ground loop and RF problems will occur.

The entire service manual with complete diagrams can be downloaded from the KenwoodMics Yahoo forum. This is an extremely low traffic forum. It is associated with this forum. Everybody on this forum should join KenwoodMics.

From: dlwstereo
Topic: 6858 Message: 6858

The TS820 Service manual Receiver alignment procedure state the SSG used be capable of 0DBuV to 120DBuV. Can someone in the group tell me what microvolt level they are using as 0DBuV @50 Ohm reference ? I have some receivers that specify 0DBuV is .5uV @50 Ohm and others specify 0DBuV equals 1uV @50 Ohms.

D.Windle

6860. TS-830s distorted TX and distorted sidetone

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-03-04 21:15:51 UTC
From: pgweber
Topic: 6860 Message: 6860

Hi all,

In CW mode, my TS-830s has developed a nasty distorted rasp in the sidetone audio, and when monitored on another radio, the TX output is also distorted. It's not hum, it sounds like there are higher frequency components. When it first appeared, turning down the carrier control helped, but now it's all the time.

I'm new at troubleshooting (at least to this level!), and I've changed the DC filter caps on the audio board, and checked the sidetone circuit, which looks OK. The HV caps measure a little over 100 µf. All the diodes on the rectifier board check OK. I've substituted new driver and final tubes with no change. I can see a distorted sine wave on the STB line when I key the TX.

Next I think I'll look at the signal at the grid of the driver tube.

Any ideas would be greatly appreciated!

Thanks,
Pete

I have one car that looks great on the outside, but has been a total lemon on the inside, and has cost an arm and leg to keep it on the road, and....I got it free...with only 35,000 miles on it....It turned out to be a very bad deal. It is parked and sucks with only 50,000 miles. I have replaced the transmission, fuel pump, power steering pump, radiator, power steering fluid feed tubes. This car is a total piece of crap. Oh yeah the A/C compressor is dead too. This is the last American car I will ever own.

Before I get bashed, let me point out that the U.S. still manufactures some darn good ham gear.

I have another car that does not look too great on the outside, but has been almost zero money to maintain. It now has over 100,000 miles on it. It is a converted company to private car and ugly, but nearly 30 miles per gallon and takes me to work every day. Just did the second brake job on it, and was able to shave the original rotors for the second time. It still has original brake shoes with about 20 K left to go on the rear.

Moral of the story....Looks are not everything...I will be glad to take a ding or two for a rig that works well over a pretty one that is a P.I.T.A. and a money pit.

My suggestion before you are not able to get money back is to find a ham close to your geography that knows the 830 and have him or she come over to play with it and give you an opinion. The fact that you were able to buy it with any money back warranty at all with the slimy dealers that are selling ham gear out there lends credibility to the seller.

The 830 has a great reputation and is still considered a sought after piece of gear way past the end of its production. I have a TS 820 and the reciever section is a little better than my 2 year old Icom.

Just remember that a bad tune up process will do more damage to your finals that multiple years of ragchewing.

Topic: 6839 Message: 6862

hi
I have an 820 which had a ding in the same place
fan housing knocked in slightly and the coax conector knocked slightly
my point is the metal used for these back plates is substantial
but very soft what I suggest is to some remove the fan housing and coax
socket and a little pressure in the Wright place one should be able to
straighten the rear plate it involves a bit of work ...can be don easily
mostly these dings are done in postage and inadequate wrapping
and to smaller box a radio should have 2.1/2 inches clearance all around
minimum radio should be wrapped in four sheets of bubble wrap and in
the bottom of the box that it will travel in place a layer of 2"" of Polly
foam beads and also remove the feet
then place the radio in the box taking particular care of the front
(don't want to drive that vfo knob back into the radio) thetas another
story..... fill the box with the rest of the beads and push in tightly
and seal the box then shake the box should be a very slight movement of
the radio inside next job is to double box it a box from a supermarket
(THEY HAVE PLENTY) cut to size of original box and place around the radio
carton tape up address and post

the postal people work with wire cages and fork lifts a lot of these
packages get tipped into the containers from a height which we would
cringe at very little hands on work these days and they do not have a care
how they handle your parcel the best compliment that you can receive from
the recipient is when he moans about how long it took him to open the box
and a mess all over the radio room floor
would you have a mess over the floor or a broken radio I know what causes
the least grief
a voice of experience who has seen some sorry packing and a dozen story's
to tell vk6ycj

You may be able to place a sleeve from a PL-259 on the SO-239. Using a pair of channel locks carefully pull the dent out. Then check for any broken ground connections and tighten up any screws in the area.

Rigs getting bent by the antenna connector that sticks out is quite common. I have UN-bent them this way many times. If it seems to work OK, and the price was right, I'm not sure that I would sweat this dent.

I'm using a 300 watt dummy load for troubleshooting. The problem
also exists when transmitting into an antenna (center fed Zepp,
balanced feed line, and a tuner).

Thanks!
Pete

6866. intermittant TS-820 meter

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-03-05 20:07:15 UTC
From: nigel4416
Topic: 6866 Message: 6866

Hi All
I posted some days ago about a problem with a meter fault on my TS-820. Thank you for the responses. I also received an e-mail from Bill Hall KZ5CW but got a failure notice when I replied to his e-mail. This fault is still driving me nuts. I have had it on and off for the past two years and have cured it, in the past, by using my YL's hairdryer as I think the rig gets damp. I read somewhere on the internet that the IF board is prone to faults if it gets damp! But this time the hairdryer has not worked
Some time ago I noticed that the rigs meter on receive started dancing around with no incoming signals. I then noticed that the meter was not responding when I was peaking the drive on tune up (meter switch to ALC). If I turn the RF gain control fully anticlockwise the meter should move to end scale (full deflection), sometimes it does this but more often than not it reaches half scale and dances around. The meter works fine when monitoring I/P current RF output and HV when transmitting but dances around when monitoring ALC when transmitting.

On looking at the circuit the ALC and receive path goes through RL-3 before going to pins 14 & 15 (SM on IF-3) on the IF board. Working back - the signal comes in to the IF board from pin 6 (AGL on IF-3) going through Q4 and Q5. The AGL path comes from RL-14 on the relay unit and then back to pin 7 (AGC on RF-1) on the RF unit and pin 11 (AGC on IF-3) on the IF board.

I have cleaned all the pins on the IF board, I have cleaned the pins and contacts on both relays RL-3 and RL-14 and I have continuity checked the above signal paths. I can't see any dry joints on the IF board and cant see anything loose. I have made sure that the screws on the IF, RF and relay boards are tight and I can't seem to make the fault better or worse by tapping any of the wire looms or boards. My next step is to borrow a decent oscilloscope and try and trace it through that way. I am still convinced that the fault is on the IF board. If you can offer me any assistance I would be most grateful.

Thanking You
73 Nigel

6867. What is the "gold edition" TS-830S?

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-03-06 05:11:53 UTC
From: ke9zm
Topic: 6867 Message: 6867

Was wondering what is the "Gold Edition" of the TS-830S? I did a bit of
research on the internet and it seems that the only difference is that
there is a gold label under the tuning dial. Other than that, no
difference. Plus, someone posted elsewhere that there are more gold
editions than non-gold.

I searched this news group and found this.

==========
Okay, I have just enough information to be dangerous here...I know that
later 830's had an updated MuRata filter K-12 installed in place of the
earlier K-5 filter...I have confirmed that mine is a later production
model,
a so-called "gold edition" as it is commonly referred to, with the K-12
filter...I don't know if this is a meaninful factor related to the
signal
path and its dynamics as described by Walt in his 820.
==========

Any more info on the "gold edition"?

Thanks
Gary / ke9zm

6868. Re: [TS-520_820_530_830] TS820 Alignment

Yahoo group: TS-520_820_530_830 (2006)

Topic: 6858 Message: 6868

The confusion may be whether the 0dBuV (1uV) is measured at the antenna terminals of the receiver or whether it is the source voltage of the signal generator. Signal generators have a defined output resistance e.g. 50 ohms, which is in series with the source voltage. When correctly matched with 50 ohms, then the terminal voltage is half the source voltage. So an internal signal generator voltage of 0dBuV (1uV) will be 0.5uV at the terminals when terminated in 50 ohms.

6870. Re: [TS-520_820_530_830] TS820 Alignment

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-03-06 16:47:48 UTC
From: Dennis Windle
Topic: 6858 Message: 6870

Isn't the loss across the 50 Ohms usually already considered on the signal generator Output Level control ? ie: when for example it is marked off as XDBM @ 50 Ohm, X is what is seen after the series 50 Ohms and at the receiver ? Or the SG Output Level control may be marked off in volts @ 50 Ohms (uV,Mv and V), hasn't that also considered the loss across the 50 ohms and the setting should reflect what would actually be seen at the receiver ?

Subject: Re: [TS-520_820_530_830] TS820 Alignment

The confusion may be whether the 0dBuV (1uV) is measured at the antenna terminals of the receiver or whether it is the source voltage of the signal generator. Signal generators have a defined output resistance e.g. 50 ohms, which is in series with the source voltage. When correctly matched with 50 ohms, then the terminal voltage is half the source voltage. So an internal signal generator voltage of 0dBuV (1uV) will be 0.5uV at the terminals when terminated in 50 ohms.

I believe that both notations may be used, but that it isn't always clear which one! I have no doubt that professional signal generators will be very clear on this point and I expect that it will be the source voltage within the SG that is specified, together with the source impedance. Perhaps others in the group can comment.

I suppose one problem is when the input to the receiver is not actually 50 ohms resistive, which may apply to most rigs. In this situation it is better to specify the source voltage within the SG.. This is then closer to real-life, where the signal applied to the receiver is from an ATU that has transformed the antenna into an equivalent series resistance of 50 ohms (a result of having set the reflected power to zero on transmit).

6873. Re: [TS-520_820_530_830] TS820 Alignment

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-03-06 19:34:31 UTC
From: Dennis Windle
Topic: 6858 Message: 6873

If the SG output level notations are for source voltage, then for example in setting the S-Meter for an S-9 reading the manual states "set the SG output to 40DBuV and adjust VR2 on IF board for an S-9 reading" if the SG setting is source voltage then the receiver is actually seeing 1/2 the source voltage for that S-9 adjustment ? At the SG If the source 0DBuV is referenced to 1uV into 50 Ohms, then 40DBuV = 100uV and with a 50% loss across 50 Ohms the receiver would see 50uV = 34DBuV. Question is whether the receiver adjustments are already considering the loss across the 50 ohms when they specify a DBuV setting of the SSG output for the adjustment or does one have to compensate for the loss and provide say the full DBuV amount to the receiver specified for the adjustment ??

6874. TS-530SP DIED!!

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-03-07 06:58:09 UTC
From: A. Newell
Topic: 6874 Message: 6874

my 530sp had been a little interminant during tune up, (flaky meter deflection w/drive, like something was loose)i was in qso, and radio had been on for an hour or more, when i lost tx in the middle of a transmission. the rx also dropped from abt 20+ to s7. i smelled a little burnt smell, and pulled the cover. the smell was comming up near the 12by7a. if i turned off the heater, i would get the rx back. i can't find anything burnt, and the driver was new. could it have a grid short? or what do ya'll think?

tnx,

"john" kn4nn

6875. Re: [TS-520_820_530_830] TS-530SP DIED!!

Yahoo group: TS-520_820_530_830 (2006)

From: Walt Breining
Topic: 6874 Message: 6875

Well, the first thing that I would do is to try to see where the smoke came from. I would then remove the 12BY7 turn the rig on without the filaments on and see if the receive is normal. If so, turn the filaments back on and see if the receive drops.

If the receive does drop, see if the lights dim and turn it off quickly. If it starts looking like there is a load on the power supply, you should place a light bulb in series with the AC mains before proceeding so as not to damage the transformer while troubleshooting. Be sure that you have the correct fuse installed!

On the other hand, if everything seems to work ok with the 12BY7 removed, you need to find where the magic smoke came from. Likely a choke coil or resistor on the RF board.

Things to check would be L-38 and L-39. R41, R37 and R35. My diagram is blurry so these numbers may be in error but I tried.

Also consider the possibility that a final may be shorted. If this is the case, look for fried components on the final and HV board, particularly the resistors associated with the final screen supply. If after removing the 12BY7, everything acts normal, key the rig on SSB with the 12BY7 removed and see if you still get 60 MA idle current, or close. If so you can probably look somewhere other than the final or HV board.

Although I mentioned the final board to be thorough, I think that you are on the right track, most likely the 12BY7 shorted and fried a coil or resistor near it in the process.

Hope this helps, let us know what you find or how you do.

Maybe it is me that is fuzzy not my diagram.
The part numbers I gave you are to an 830 not a 530, but the other information is general enough to be the same. The parts I would look for that might be fried are a choke in the plate circuit, a choke in the cathode circuit, and resistors particularly below 1000 ohms associated with the screen or the cathode. Also anything in the control grid circuit.

I buy my glasses at the Dollar Store.

tnx walt,
i get the 60ma idle with the 12by7 out, and good rx.
i think part of it, was the 12by7. i put a known one in, and i can get
100w tx on 75m & 70w on 20m, but 35w on 40m & 20w on 10m. also no alc
meter deflection while tuning or talking. plate current is low 200ma
on 70m, hv is 900. the 12by7 that was in when it quit was very hot
compared to this one.

6879. Just received a "new" ts-830s and have some problems...

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-03-07 22:33:24 UTC
From: jovem_cao
Topic: 6879 Message: 6879

Greetings everyone and thanks for having this wonderfull list :)

I am a proud owner of a Ts-520se but have seen a good looking TS-830s and decided to buy it.
It seems to work fine, but It seems to have some problems:

When doing the tunning procedings, when I switch the meter to RF and close the keym the meter goes crazy and hits its maximum (although it is throwing out about 125Watts metered on the antena tunner).

Comp meter seems to be dead, since I get no reading talking to the microphone, and while adjusting comp level :(

Monitor function (to listen to my voice while emiting) doesnt seem to work... I tryied this with several different mic gain and AF levels...

Finnaly, and this is just a question, my Ts-520SE puts out 150W.. this 830s puts only 125W... are these normal values, or should I start thinking of buying new valves for the 830?

Thank you in advance for all the possible help I can get. I am not afraid of opening the transceiver and trying to fix some stuff, but only If you can direct me on the right way since I am still a not very experienced ham operator with limited electronic knowledge :) (but willing to learn ofc)

Hmmm meanwhile i discovered I can adjust the Watt meter with that
little bolt on th back of the radio... ehehe
That problem is solved, but other doubts have arrised:

I only get decent ALC reading using a MC-50 with Mic gain on 8 or 9
position. I usually use it on 6 on my ts-520se. Is this normal? Can
this be related to no monitor sound?
I also didnt notice any difference with the processor on/off...

thanks once again,

73 from CT2IWG, Sergio

6881. Re: TS-830s distorted TX and distorted sidetone

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-03-08 02:22:55 UTC

Topic: 6860 Message: 6881

The problem is fixed!

The previous owner had performed a QRO modification: On the rectifier board he had cut the trace that supplies 210a voltage to R13. He added a jumper to connect that circuit to 300B voltage. This caused R13 to eventually fail, causing the distortion on the STB line (STB is derived from 210a through a voltage divider consisting or R13 and R12).

Sidetone and TX output are clean once again.

By the way, this QRO mod increases the screen voltage to a level that causes premature failure of the final output tubes. I could actually hear arcing in the tubes on occasion.

Thanks to all,

Pete

Hi John

I am not familiar with the 530, but I have recently repaired an 830,
which some people say are very similar. I stand corrected if not.
I have posted the 830 problem and solution in this group, but I will
give you a brief description if you missed it.
The 830 had good power up to 40m. Power slihtly reduced on 20m, nothing
on 17m, and very low output on higher bands.
No ALC on 17m, and very low ALC on bands above 17m.
A shorted choke/inductor feeding the 12BY7 and a leaky bypass capacitor
were replaced and the 830 is back on air.
I suspect that your 530 may have suffered the same. If the 12BY7 draws
excessive current, it will take the RF choke out.
The choke's value in the 830 was 470uH and measured about 4 Ohms. If the
530 has a similar value, then you can check for the same.
The faulty choke measured much less than 1 Ohm.
All the best

I dont mean to flood this mailing list, but since I have been exploring my 830 I have found some other flaws...

The NB doesnt seem to have any effect and I found that the switch seems to have only one side conected:

http://img455.imageshack.us/img455/7/dsc016153wv.jpg

and

http://img455.imageshack.us/img455/1777/dsc016160su.jpg

I wonder if the Moni switch is also like that one... I have to try to open the down side of the transceiver tommorow...

After I key down the microphone, receive goes down a lot, I have read that it should be from the RC/TX switch... need to clean that too... Any tips to locate it fast?

The guy that sold me this transceiver told me it had been Reviewed by a tech... Yeah .. right.. :|

I assume that with the good 12BY7 you get normal receive. There are two possibilities. First, the replacement 12BY7 could be weak. This would impact the higher frequencies more.

The second and most likely problem is that you fried a component when you saw the magic smoke escape. I do not have a diagram of the TS 530 but you should look for resistors particularly under 100 ohms that are open or choke coils that are open or shorted. Look in the control grid or cathode circuit of the 12BY7 for these. Also, look around the 12BY7 screen grid circuit and measure the screen grid voltage on the 12BY7.

A relay may need cleaning. There is a level control for the monitor beside the rig volume control. Probably using just one set of contacts on a switch is normal.

Greetings sir and thanks for the tip.

I have been exploring more and NB ,ight be working, although it is not very obvious... processor might need a little tweak, but works.

Monitor does nothing. I seen on the service manual there is a monitor volume adjustment on the left side of top PCB. I tried adjust it and nothing happens. I wonder if it might be a problem with the clamp conectors that I have read about that might have bad contact.

My doubt is, which of them has has anything to do with the Monitor circuit... If anyone knows would be a lot of help...

ps: i cleaned the tx/rx relay, and it works fine now :)

Hummm I removed the VFO, and the little PCB to the left seems to have
two missing point on the PCB.. please see the photos:

http://img529.imageshack.us/img529/5721/comp18tw.jpg

and

http://img529.imageshack.us/img529/9923/comp21bd.jpg

Is this normal? Does this little PCB have anything to do with the
Monitor circuit?

Thanks :)

Hi Walt.

Regarding your question to Joan, I experienced the same problem that she did, and she coached me thru the repair. I have both radios (530 and 830), and checked their schematics. The component identifications for both radios are L36, 470 microhenry, and C74, 0.01 mfd, and they are in the 12BY7A plate circuit on the RF Board. Access for replacement can be from the bottom by removing the metal plate under the RF Board which is easier than removing the RF Board itself. Both components went bad in Joan's radio, and only the inductor went shorted in mine. With an ohmeter, a good inductor measures about 4 ohms. My bad one measured about 0.2 ohm - so at least that gives you an indication if you don't have a meter to measure inductance. With the bad inductor in my 830, I could receive on all bands, and transmit on all bands except 15M where there was no ALC indication or power output. The affect on Joan's radio was a little different on the higher bands, but that was probably because the capacitor was also bad in her radio. But, you should pursue that with her if you need to. Hope that is of some help.

73, Bill, K5GCW

Joan:

Was this choke in the plate circuit or cathode circuit or elsewhere. In what
circuit was the bypass cap ?

Hello Frank,

I think there was never a service manual made
for this antenna tuner. There are only a hand full parts in it ,so I think
it was not necessary to do so.

Bill, I am glad you got the TS-830S 15 meter band working. I have a great idea Bill and that is for you to compile all this information into a format that will help others if they have these problems with the TS-830S. What do you think? Also thanks to Joan for all the information she has provided. Good to see you again Bill.

Regards,

n9wb <n9wb@...>

Bill, I don't mean to embarass you here but I was rather amused by your assumption that I wear a skirt. Authorities, banks and many people have done the same thing, except I am born of male gender. I was born in formerly Dutch New Guinea and my parents named me after a governor general. It was never an issue until we migrated to Australia where it is a common girls name (and all over the world). I am not offended by it at all and think it is rather funny. I can tell you a number of funny stories, but I wont go there. I thought it be good if the group was aware. I have really enjoyed this group. There is an excellent exchange and wealth of information available. Well done people.

Joan

6897. DG-5 Problem

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-03-10 02:24:57 UTC
From: The Bandit
Topic: 6897 Message: 6897

I recently purchased a Kenwood DG-5 at a fest to use with my TS-520S. All digits light, but the frequency is off by about 2mhz and the main tuning knob does not change the display frequency. I saw these same symptoms listed in the kenwood service bulletins and they suggest cleaning the rca jack on the DG-5 which I did with the same results. Does anyone have any other ideas, or know how to tell if the rig or the dg-5 is at fault. The guy selling the DG-5 said it worked fine (although that doesn't mean much these days).

Or if anyone in the S. FL area has a TS-520S that would be willing to let me connect this to, to test it, that could tell for sure.

Thanks!

6899. Re: [TS-520_820_530_830] DG-5 Problem

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-03-10 15:02:18 UTC
From: Brent W. Baum
Topic: 6897 Message: 6899

Two things cause this same fault with my DG-5. First, loose connections: try lightly squeezing the fingers of the various RCA connectors toward the center of the plug to tighten the fit. Second, a loose VFO plug connection: make sure your VFO plug or jumper on the back of the radio is making a good connection. The final quick fix is one many of us don't like to admit, are the cables connected correctly?

Good luck

>>> flabandit65@... 3/9/2006 7:24 PM >>>

I recently purchased a Kenwood DG-5 at a fest to use with my TS-520S. All digits light, but the frequency is off by about 2mhz and the main tuning knob does not change the display frequency. I saw these same symptoms listed in the kenwood service bulletins and they suggest cleaning the rca jack on the DG-5 which I did with the same results. Does anyone have any other ideas, or know how to tell if the rig or the dg-5 is at fault. The guy selling the DG-5 said it worked fine (although that doesn't mean much these days).

Or if anyone in the S. FL area has a TS-520S that would be willing to let me connect this to, to test it, that could tell for sure.

Thanks!

Hi Sergio

"... I only get decent ALC reading using a MC-50 with Mic gain on 8 or 9 position. I usually
use it on 6 on my ts-520se. Is this normal? Can this be related to no monitor sound?
I also didnt notice any difference with the processor on/off..."

The MC-50 has 2 possibility of Mic-Impedance, low + high. You can change this, when you turn the connetor, which is going into the mic, for 180 degrees! So this could be the low ALC/Comp-Level problem.... who knows

My 820 is grey, thus I have the GREY EDITION, and it was indeed
limited production. (To the number of buyers that bought them)

Thanks for the tip, dear Daniel, but it is on the right position...
I guess the gain from the 830s is different from my 520se...

Thanks anyway for the possible help :)

Sounds like your DH button on front panel of DG-5 in pushed "in"
[on]. Make sure this button is "out" [off] and function is on
VFO not "fixed".

6906. Buying these Hybrid radios on ebay (& elsewhere) and packing...

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-03-11 04:03:48 UTC
From: ke9zm
Topic: 6906 Message: 6906

I thought I would pass this along based on my experience and maybe suggest some ways you can avoid a smashed radio during shipping.

In the recent past I purchased three Kenwood Hybrids - a TS-520S, a TS-820S and just recently a TS-830S. I can report that they have all become friends and are getting along nicely.

The issue is shipping these things. A kenwood Hybrid is not an ICOM 706 that maybe weights a few pounds. Kenwood Hybrids weigh about 40 pounds and so getting these radios from point A to point B in one piece and not damaged is a challenge.

I just purchased and recieved my "new" TS-830S. The seller packed it as follows. The radio wrapped with about 4 layers of thick bubble wrap, inside the original TS-830S box, inside a second box separated with peanuts and tighly sealed. It was sent FedEX insured.

When it arrived it had a pucture in the side of the box. The puncture hole went through the first box, through the peanuts, through the second box and through one layer of bubble wrap. There was no damage to the radio. If it was not for the approx 6+ inches of peanuts, bubble wrap, and cardboard, the puncture would have hit the radio.

I also bough a TS-820S. The seller packed this one in the same manner but seems the box took a hit and smashed the VFO knob. I had to disasseble and reassemble the varios VFO knob components and dials to fix this. The radio was not damaged.

I bought a TS-520S from a ham radio store. The box that it came in was enormous. It was double boxed with about 10 inches of space between the boxes filled with peanuts.

So, what's the bottom line? Two of the past three radio's I bought had a tough journey from the shipper from point A to point B.

To avoid this, my suggestion is that sometimes you need to educate the seller on how to pack these radios. Some folks on e-bay are not hams and they sell these radio not having the slighest clue as to how to pack these to avoid damage given their weight. You will lose in this situation when you open the box.

On ebay, there is a box at the checkout that offers you to send some info to the seller. When in doubt about packing, tell the seller of communicate directly with him/her on how to pack the radio.

Best packed was what I got from the ham store. The enormous box provided about 10 inches of "crush space" and "puncture space" around the radio in a second box.

Better safe than sorry. The bigger the outer box the better. Tell the seller how to pack the radio to avoid damage of your new old radio. In my case, two radios out of three with potential and real damage is not a good record.

From: Roberto Baca Barnard
Topic: 6907 Message: 6907

My TS820 RIT control pot works okay, but signals sound just a tiny bit "chirpy" as I move the knob, and only when moving knob. Just dirt? Carefully sprayed (air) AF pot to good effect, ditto VFO shaft. Please advise..tnx. 73 WB7AVF/2

Question two: anyone got a CW filter for the TS820? Mine doesn't have it installed and the space on the board begs for it.

Here's something else to try, if you can get your hands on any of it. I get computers, monitors and parts sent to me, some of the shippers use what I think is formaldahyde (I am not going to spell check that!) that gets sprayed in wet and molds itself around the component. I had received a printer back from factory repair and the packing it came in fit very nicely, top and bottom on the TS530S I was sending out for repair. I took the advice of the person I was shipping it to and put something extra around the dial knob and filled everything else with the plastic peanuts, it was suggested that I put the peanuts in plastic bags, it seemed to add more protection than having them loose in the box. The final shipping weight was about 28 pounds, it didn't add that much on to the cost of the shipping and I felt it was worth it when I got the report that the radio had reached its destination in good condition.

I use insulating dense foam on the bottom of my shipping cartons. This is found at home centers and if you stroll in on a late Sunday or early Monday morning you may be lucky enough to buy a broken piece for a buck or two or three. They come in 4x8 sheets and can be up to 2 inches thick.

I have also used spray foam insulation to fill voids in a shipping carton and to ensure that the inner carton won't shift around. There are three types of this foam. One is minimal expansion and the other will expand to several times its original volume. These are both urethane based products and require acetone to clean up. (nail polish remover) They are also found in the building supply section of the big boxes with the other insulating products.

The third type is a water based product made by DAP. This is found in the paint section and it has the advantages of a water clean up and minimal odor. The only draw back is that it takes a bit longer to cure and doesn't expand as much as a urethane based product.

In any case, if you do use this foam it's a once and done application. No matter how much you try to clean those valves and spray parts you can never use the rest of the contents left in the can.

I hope these tips help some of you folks who are shipping these 40 pound charms. I have on occasion paid extra to have an item shipped exactly the way I wanted it to be. This way it absolves the shipper of any responsibility if he or she follows your instruction to the letter.

Also, don't be afrrid to ship an empty carton to a seller to use to ship back your item.

Gee, odd that you should mention that. I was talking to someone today and he sent his radio to Yaesu for repairs. It came back sealed in foam. We think it works as folows. The radio was placed in plastic bag and then placed on a box. Then the radio was sprayed with a foam that hardens and expands. So, the end result was the radio packed in foam that is molded around all the knobs and dials and firmly held in the box.

I saw some stuff at Home Depot that is used for sealing open spaces, like around windows. You spray it in and expands to 100x and then hardens. Maybe thats the stuff. Worth an experiment to see what happens.

From: w3iz
Topic: 6912 Message: 6912

Hi Folks.
Q. Do you know what makes a TS-830 or a TS-520 really perform well?
A. A really good antenna.

Before I put this on the auctions I thought I would offer it out to the group.

I have a Cushcraft A-3 that has been completely rebuilt and has all new SS hardware and new balun. All the traps are as clean as a whistle with no dirt or bugs.
The elements are all assembled so it will arrive sub assembled making it a 20 minute job to get it to the tower or mast.

All the connections have been coated with No-Alox anti oxidant for years of trouble free operating.

These antennas are real workhorses providing 8 dB gain on a 14 ft boom. Great for small lots. Many DXers have worked over 200 DXCC countries with an A-3.

A new A-3 sells for $429 and you have to put all the little parts together. I am selling this one for $200. I can ship at the buyer's expense and I could also meet someone within 100 miles of Hartford, CT.

I will also be traveling to NJ & PA in April and could arange a meet then.

Please contact me off of the reflector at w3iz@...
or my phone is 860-584-1403.

Thanks for the bandwidth.

Don't get this stuff on your hands and clothes when it's coming out of the can. It's a bear to get off. Even after I finished what I was trying to seal, which turned out to be messy and ugly, I couldn't get the can to stop oozing this stuff. I wouldn't put this stuff in a box with my equipment even if I had ten bags around it.

Clean the RIT pot with do-oxit or if none is available rubbing alcohol.
Also there is a mod for the RIT. I have had several TS-820's and have not
needed to do it.
I bet the cleaning will help.

The mod is on the following site near the bottom:
http://www.radiomods.co.nz/kenwood/kenwoodts820.html

I wonder if there is a small potential for damage with the
super-expansion foam from exerting pressure on the shipped product?
The safety valve is the shipping container. Hopefully it would burst
before some damage is done.

Well, I guess we used to sell that stuff to stupid people who own homes so it stands to reason that there would be the same individuals out there who ship radios.

Don't try to fill the whole box at once and leave to top open so there is room for the foam to expand. Should it expand above the top line of the carton, it cuts easily with any knife.

Just buy the gold edition.
It comes with a self de-materializer so you can transmaterialize it to anywhere.
Alternatively, TIG-weld two osmium brackets to the front plate to protect the VFO knob.

The gold edition manual also recommends:
Put a 100W lamp in the box to make it light.
Alternatively, fill the rig with helium to make it light.
Honest!

OK people, it's getting near that wonderfull time of the year, April 1st, just to keep things on track and in a good mood I will pass along something that was writen up in the Grumman club paper many years ago, and you must remember this was during the later years of the LEM project and the start of the F-14 Tomcat:

"Did you ever notice that after the water company works on the pipes, in some cases dirt and such comes out of the faucets? Same thing happens when the electric company works on their lines. You can check this out by removing a tube from your radio or TV, tapping it on a hard surface and you will actually see the dirt and stuff on the side of the tube. One quick way to eliminate dirt getting inside your expensive equipment is to install a simple trap where the electric service comes into your house. There are three leads, hot, neutral and ground (please remember I am not an electrician), after turning your service off, terminate either the neutral or hot lead on a screw leave about an 1/8 of an inch gap and terminate the other side on another screw. Under this hang a small plastic tray and turn everything back on. The electrons, being lighter than dirt will "jump" across the gap and the dirt will fall into the tray, empty as often as needed>"

Great Stuff and the expanding foam used in shipped
is not quite the same. Granted they are both expanding
foam but great stuff tends to harden more whereas the
stuff used in shipping boxes tends to be not as rigid.
Thus it has some shock absorbing qualities.

That an I believe that it is injected before the box is closed
so there is no danger of damage I've seen some delicate items
shipped that way.

Dick,

You are not putting the foam in a closed container. Since it has room to e x p a n d! The fidget foam is by far the best way to ship heavy hybrid gear. I have shipped several sets using it in double boxes.

Walt, KA2NJF

I wonder if there is a small potential for damage with the
super-expansion foam from exerting pressure on the shipped product?
The safety valve is the shipping container. Hopefully it would burst
before some damage is done.

Hi to the group: I am working on a 520s with no power out.What I have done so far.
SG switch is on
cleaned relays
checked HV it is ok
NO BIAS
NO ALC
When I try to check bias meter swings down instead of up??
Tubes all light
This is a friends radio he said it worked fine one day and was dead the next.Receive and all other functions seem to be fine.

Thanks for your help....John

hi,

Not everyone out there understands what
double boxed means !

I asked the seller of the ts-520 station
I purchased to double box it and send the
accessories seperate box and I would pay for it.
No problem she says, however, the radio was sent in
one box and other gear in the other !

Luck for me the UPS crews must have been hams,
all arrived in working condition, in used walmart
boxes with cruched newspaper inside.

6923. Low receive TS520S once properly tuned up ??

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-03-13 14:19:46 UTC
From: Phono-Guy
Topic: 6923 Message: 6923

I have this problem with a TS520S, all else seems to
work to specs, proper output, and HV readings.

The positon of the Drive control that results in
the best receive volume & deflection on the meter does
not correspond to the position of the Drive control
when this radio is tuned for maximum output.
So when this radio is all tuned up properly the
receive is down. Anyone have an idea where I should
start to try and find the cause of this problem?
Could it be related to the 12BY7A?

Appreciated any and all suggestions.

73,
Clint - WS1V

6924. TS-820S Receiver Hum

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-03-14 02:14:25 UTC
From: Frank Lambert
Topic: 6924 Message: 6924

Well, I got the display problem and the audio problem "put away" and, after running the rig for a few hours, when I fired it up this evening, there was an EXCESS amount of receiver hum on the signal. Enough to make it almost distorted. I was not a "happy camper", after all the time I have put into this old rig so (I liked it a lot better in 1979.. Hi!) I did not even switch on the HV, so I have no idea about the transmit signal. I suspect C1 and C2 in the rectifier ckt. Can anyone recommend a good source for those electrolytics (show discontinued at East Coast Transistor) and, would you recommend going further with replacing all the electrolytics? I did search the archives and, saw some mention of someone possibly putting together a capacitor kit... Anyone know more about that? Does anyone have any other ideas about what might be going on? I don't have a scope so, I can't look at the ripple on the PS... This rig has been in storage for about 10 years.... Thank you es, 73's
Frank WB4OUF

6925. TS-820S Receiver Hum

Yahoo group: TS-520_820_530_830 (2006)

From: Frank Lambert
Topic: 6924 Message: 6925

A little more info. on my problem. In addition to the 60 cycle hum, I am also getting an audible "buzz" around the transformer area. I do not have the HV switched on and I thought it was the fan at first but, have disconnected and eliminated that. Also the 25 Khz marker is distorted and sometimes not there at all. Also the frequency display has gone haywire and seems unstable. I can turn the RF gain down completely and advance the AF gain and the 60 cycle hum becomes more pronounced. There is also an occasional "crackling/frying" sound in the audio. I can receive but the reception is distorted. Have not even tried transmitting with it since this problem came up.... Bad part is, this thing was working like a charm just yesterday. Would appreciate any suggestions/help. Thanks again es, 73's
Frank, WB4OUF

6926. TS-820S Receiver Hum/The saga continues

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-03-14 14:50:52 UTC
From: Frank Lambert
Topic: 6926 Message: 6926

The "hum" is fixed! There was a broken solder connection in one of the outboard VFO connectors.... Go figure... Anyway, now I have only one problem left. The VFO "stops" at the low end of 40, 80, and 160. It just gets down around the low end and then any further rotation of the VFO dial has no effect on the frequency setting and the display becomes unstable. The wierd part is that it does the same thing using the remote VFO as well....? AND...20M seems to work OK ?? Any thoughts? Thanks again, Frank WB4OUF

MY LAST POST SAID IT WAS A 520 IT IS A 530S..SORRY ABOUT THAT TO
RECAP
SG SWITCH IS ON
HV IS FINE
TUBES LIGHT
RECEIVE IS FINE.....BUT.....

NO BIAS CURRENT
NO ALC

THIS IS A FRIENDS RADIO HE SAID IT WAS OK ONE DAY AND DEAD THE NEXT
THIS IS WHAT I HAVE DONE TO DATE:

CLEANED RELAYS
CLEANED AND RESET ALL CONNECTORS
CHECKED AND CLEANED SG SWITCH (ITS OK)
TIGHTENED ALL SCREWS ON ALL BOARDS
CLEANED ALL POTS AND SWITCHES

I DONT HAVE A SCHEMATIC SO KIND OF WORKIN IN THE DARK I DID CHECK
THE SCREEN VOLTAGE SEEMS TO BE LOW 111V BUT NOT SURE.

WHERE SHOULD I GO FROM HERE ......THANKS....JOHN

6928. VF0-520S / AT-200 meter light?

From: kc2nzf
Topic: 6928 Message: 6928

Hello to all,
I am in the process of assembling an entire TS-520S station. It now consists of the TS-520S, AT-200 antenna tuner, VFO-520S remote VFO, SP-520 speaker and DG-5 digital display. This is my primary HF rig and I enjoy using it...but...Has anyone ever modified the VF0-520s and AT-200 tuner to add lights for the meters. I use the tuner monitoring the fwd pwr to adjust the load and the plate current on the rig, it would sure add to the looks of the station if all the meters were lit. I would like the displays to be the same wattage as the rig. Thanks.

First thing to do is to sort out the cause of the low screen fault, which may fix the problem. The manual shows 275V receive and 253V transmit. Possibilities are a poor joint, a series resistor that has drifted high, a leaky decoupling capacitor or a rectifier fault. I suggest checking the voltages on the rectifier unit - take care there are lethal voltages in this area. I haven't traced the circuit from the screen of the PAs to the power supply, but the screen must be run from the 300V line.

I assume that you know how to discharge the 800 V so you can work in the final cage safely. If not get back to me before you do anything.

Remove the tubes. Mark which one went where. (yea there is a reason). Be sure the plate leads and the parasitic chokes are positioned so they will not get into mischief.

Go to the SG switch. What are the voltages at the top terminal, the center terminal, and the bottom terminal. Be sure to note if they are + or -.

On the final unit board at the point labeled SG measure the voltage with the SG switch on. Be sure to note whether the voltage is + or - in each case.

Now, on the final board find a point where R5 and R6 join together. With the SG switch on, measure the voltage at this point.

Then measure the voltage on the other end of R5 and R6.

Go to pin 3 of each tube socket, be sure that you are counting the pins right and get the voltages there.

The rig will not have to be placed in transmit to make these measurements.Be careful, the 800 volts will be present on the HV and rectifier boards as well as the final cage. When the rig is turned off, it may take longer to discharge than with the tubes installed.

Page 33 of your owners manual has the final unit as figure 27.

Please let me know what these readings are with the caps lock on your keyboard turned off Hi.

Vy 73, Walt N9WB

Hi Walt and the group,

Ok took the voltage measurements you asked to see they are as follows.

SG switch top -111
center 0
bottom 0

Need I go on? All others are also 0

pin 3 both tubes
R5&R6
SG point on board

Also the manual I have must be different then yours I have one that
says TS-530S/SP/D and says Korea market only? It is the service manual.
Where to look next? ....Thanks John

John,

The "Korean Market" refers specifically to the TS-530D version, which has a single 6146B - this is dealt with on page 53 of the Service Manual. I would be very surprised if any "D" versions have ever made it to the US or Europe.

I have taken a look at the schematic for this part of the rig. The ON side of the SG switch is connected to point PD2 on the rectifier board and goes out of the board again via point SG1. There is an RF choke L1 between these points, with a decoupling capacitor C3 to 0V. Point SG1 is connected to point SG2 on the rectifier board via a section of the mode switch - this is so that the screen voltage can be reduced in the TUNE position to keep the anode current to about 100mA max - a nice feature. On the rectifier board SG2 is connected to point 210A and then via R11 to the diode/capacitor that generates this supply.

So I suggest that you check the voltage at SG2/210A. I'm not sure what it should be, but probably about 300V. If this is OK then I suspect L1 may be open circuit or C3 short circuit (or both - C3 going s/c might take out L1)

I believe that the -111V that you measured on the SG switch is correct - this is the voltage on the screen when the SG switch is OFF for neutralising.

Richard G3OTK

John:
Either the rig has morphed or I am confused. Your first post said it was a 520 ? This one says that it is a 530.

I need to know which schematic to look at.

Walt N9WB
I need to know which schematic to look at.

6939. TS-830 Bandswitch coupling

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-03-16 23:47:37 UTC
From: wohtex
Topic: 6939 Message: 6939

I read the file posted on changing the bandswitch coupling, was looking at mine and was wondering if I can just loosen the back set screws and then when I pull the bandswitch shaft out the coupling will come out with it, put the new one on and reinsert through the hole to the inside shaft???? or did I miss something in the instructions that would preclude this?

thanks
Bill

Richard and The Group,

SG2/210A 0 volts on both points everything on the board looks fine
nothing is burnt that I can see, same for the RF board I pulled it all seems
okeydokey.

hi,

http://www.nteinc.com/

for those on a fast internet connection,
you can download V 12 of NTE QuickCross
for windows no cost. you just have to
answer a few questions and you can d/l it.

A lot easier to search for replacement parts
and it links to the data sheets.

That would explain why the page numbers I gave you from my 520 manual did not match your manual.
It seems that you have no screen voltage. That comes from a board, probably called the HV board or something like that. The problem that I ran into is that I went to BAMA and downloaded the 530 user's manual. Part of the schematic was covered by a sheet of notes and the covered part is where the source for the screen voltage is.

So I went back to get the service manual. Now whenever I try to access the 530 file I get a page not available message. So I am trying to get a complete diagram to help you more.

With very great thanks to Mr. Richard Harris, G3OTK I now have a very good copy of the manual and schematic for the TS-530. So we can continue.

For those who have just tuned in to the continuing saga of "[TS-520_820_530_830] 530 NO OUTPUT" John's TS-530 has no output. We have determined that he has no screen voltage.

John.

You have a board labeled "rectifier unit". This is the board that supplies the SG voltage to the SG switch. There is a point on this board labeled PD 2. Check the voltage at this point. Then check the voltage at SG1. Also measure the voltage at SG 1 and TUN. Do this with the mode switch in CW. No need to put the valves back in yet. This should be a + DC voltage so set your meter accordingly.

Vy 73, Walt N9WB

Thanks for the input, when I changed it last night I found out you need to remove the shaft 1st so when you bring the coupling out of the hole you can tilt it upward to clear parts on the circuit board. Frankly I had more trouble getting those little spring clips back on than anything else.

Hi All::
K7GNO
New to your group..

I have a question??

Can some one explain what "valves" are from this statement..

Do this with the mode switch in CW. No
> need to put the valves back in yet.

I am usually pretty savvy on stuff but I am Clueless what the "valves" is..

Someone Please enlighten me..

Gene

Gene,

"Valves" are what vacuum tubes were always known as in the UK. No one in the UK would have known what a "vacuum tube" was apart from hams brought up on the ARRL Handbook and HF comms!

The UK name probably dates back to the first vacuum tubes circa 1900 which were diodes and hence one-way "valves" for AC.

Hi and welcome to a great group.

The difference between a valve and a tube is that a valve has an anode instead of a plate.
In the UK it rains a lot, so anodes are used to neutralise raindrop resonance.
The gold edition is fitted with both.

All the best for April 1st.
Dave F4EYK

I was really lucky. My 820s was shipped in the original box with the original foam and overfilled with peanut foam. The original box was wrapped in fat bubble wrap where the tape could be removed without damage to the original box. The original box was placed inside of another box with air bags and overfilled with peanuts to fill in the gaps. It had both manuals with it, and on the inside cover, the service dates, who did it and what was done. I would not think twice about buying from this guy again, and would in fact seek him out. I think I paid about ten bucks over the going rate for shipping, plus insurance, which he required both. The rig was a 9.8 on appearance, and the only thing that I have done to it in four years is replace the T/R relay. It still has the original 2000 tubes in it that crank almost 100 watts out.

Like I said, I was really lucky. The seller.... was really a pro.

Rig=TS-520SE.

Have tuned up my old 520SE; dummy load.
Appears to be working fine, but RF
out measures only 55 watts max at TUNE and CW. ALC and HV all ok
per specs although my 'load' control needs to be set at high 2pm
position and 'plate' at top of selected band.
Drive control maxs at 1pm slot. Carrier at 12 o'clock, mic at 3
setting.

Is this just old, weak 6146's? Not a real issue as I plan to use rig
to drive amp on upgrade -- but would like to get 520SE in mint
shape. Output looks ok on my sm-220. Tune-up used old Drake HF filter.

TS-520_820_530_830@yahoogroups.com writes:

Can some one explain what "valves" are from this statement

Valve is British for what we call tubes. Actually, although I am an American
the term "valve" does describe the action of a tube better. Look at a normal
triode, the grid acts as the gate in a valve to control the flow of current
from the cathode to the plate.
I build model steam engines from British magazines and plans and there are a
lot of terms that you need a translation table to read what the Brits write.
LOL.
As one English friend told me, You Americans drive on the parkway and park
on the drive way while we do it the other way around. They say "round about"
for what we call a "clover leaf" and so on.

Bill:
I noticed that you were only getting 55 watts at both tune and CW? If this is correct, it is a clue that you may have screen voltage problems.

OOPS, I noted that you said the Carrier control was at 12:00. Put it fully clockwise.
If you have a Drake low pass filter in line. remove it, at for now.

If it still reads low, please check the following:

Be sure that the carrier control is fully up.
Be sure that you have the Drive peaked for maximum with the multimeter on the rig set for ALC.
Start with the load control midway, peak the Plate then peak the load.
Repeat this process a couple of times. What is the output on 40 meters compared to 28.300 on 10 meters ?

Are you sure that the watt meter is reading correctly? Are you sure that all jumpers from the rig to the watt meter and from the watt meter to the dummy load are good?

Bad resistors on the HV board can cause this problem. After you respond to the above I will go into more detail. Do you have a volt meter available ?

6970. WARC Modification on the TS-830S Confusion

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-03-19 08:12:09 UTC
From: Daniel
Topic: 6970 Message: 6970

Hi to all

I've a small confusion on my side about the WARC Mod on the TS-830S. There are two article here:

1. In early TS-830's, the WARC transmit was not enabled.
If this is the case, solder a jumper wire from Pin 12 of IC-23 to ground on the DIGITAL UNIT PCB. Ground can be obtained at Pin 8 of IC-4.

2. POWER OFF AND UNPLUGGED! Remove top and bottom covers of the rig. Rig placed on it's left side so that the side with the final tubes is UP and the front panel is to your LEFT
(to orient the rig to the picture). Now locate connector 7 on the AF unit. This is the PC board on the upper left as you face the bottom of the rig. Look for the blue wire on the third connector from the left- bottom edge of the AF unit. In the photo you can see that it is the 4th wire from the left on connector 7. Cut the wire, then insulate the ends with heat
shrink.

So which one is the one who is running properly?

Example 1.
I didn't find the DIGITAL UNIT PCB. Perhaps it is named different (which Board number?)

Example 2.
Which Board?

Daniel, HB9DDS

6971. Re: [TS-520_820_530_830] 530 NO OUTPUT

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-03-19 11:07:14 UTC
From: Walt Breining
Topic: 6933 Message: 6971

John:

Voltage should flow through R-11 from 210 B To 210 A. R-11 is a 470 ohm resistor on the rectifier board. Since you get 0 V at 210A and 248 V at 210 B, the resistor is open or there is a bad connection on the bottom of the rectifier board. You should replace this resistor. But don't turn on the radio yet!

Before you do so, If the resistor is open and it is not a bad connection, there is a reason why this resistor failed! While it could have failed from running warm for years, it is more likely there is a short somewhere on the 210A side of this resistor causing it to fail.

Next step:

The following tests are done with the radio unplugged. and discharged.

One place, R-11, 210 A feeds is the screen of the 12BY7 driver tube on the RF board. A likely suspect is C-73 being shorted. This is a .01 uf capacitor at 500 volt rating.

You can check it in the circuit with an ohm meter. If it shows less than 1000 ohms across it, you will then have to take it out to check it. Temporarily turn the SG switch off to check it in the circuit. Don't forget to return the SG switch to on after checking. It should show a open circuit when removed from the board.

Replace it if it is shorted. Be sure that the replacement is rated for at least 500 V.

To find it, if you are looking down on the RF board you will see the 12BY7 to the right of this tube there are two rows of can type coils. The ones closest to the tube are labeled AUX. These are L 103 and L 23. Just off the end (side) of these coils in the direction of the tube is C-73. This is not the capacitor in the space between these two coils.

210 A also feeds C-86.on the IF board. This is a 22 uf 350 V capacitor on the IF board. This is a can type capacitor. It is the filter for the screen supply.

To test this capacitor, find plug #3 on the IF board and unplug it. It is near C-86. Locate pin 1 of plug #3 labeled 210 A. and pin 2 labeled G. Temporarily short these two pins together with a screwdriver for a couple of seconds. Place your ohm meter in RX1 or RX 10 and place the black wire on the 210 A pin. Place the red wire to the second pin next to it labeled G for ground or the top of the capacitor can if it is bare. Yes, I said the Black wire on pin 1/ 210A. Observe the meter. At first it will show a short or

very low resistance, but then the resistance will rise until it is quite high. To double check this, short the pins as described above and repeater the above procedure. If it shows a very low resistance and stays that way, it will need to be replaced. Be sure that your ohm meter leads are not touching together giving you a false reading.

Replace C-86 if it appears to be shorted. If you do replace C-86 you may wish to replace C-87, C-88, and C-89, however C-86 is the only one that is associated with the 210 A source. Be sure that the replacement is rated for at least 350 V.

If R-11 has been hot, it could have increased in value. This would cause the screen voltage to be low and thus the output low.

If you think that the tubes are weak, go to this groups home page, TS-520_820_530_830, go to links, and read the article on testing the finals. This the Coors Bill method. He works on these things all or the time.

Also be sure that your watt meter is reading right and that the carrier control is fully up when peaking and measuring the output. Incorrect watt meters cause a lot of needless worry.

Put a drop of sewing machine oil or Mobile one in all the band switch bushings. Particularly the ones after the coupling that leads into the final section. If these get stiff, the coupling will break.

Glad that you got it running. It is a good rig.

Topic: 6977 Message: 6978

Hi kevin.
Congratulations on the upgrade and the new radio.
In the RF position the meter give a relative output reading. There is no scale for power out. The manual says that the rig should be adjusted for a 2/3 deflection of the needle in the RF position.

Always check the IP current when final tuning the rig.

If you take the IP current in mA and multiply by the HV you will get the input power to the final stage. Your output is aproxamately 1/2 of the input power.

6979. R: New 830s Owner - How Do I Determine Wattage Output?

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-03-21 08:05:57 UTC
From: P. Coppin
Topic: 6977 Message: 6979

Congratulations for upgrading and for TS-830. Three months ago I bought my first TS-830. I tested lots of rigs in about 30 years of radio ham but I am very impressed as for the 830. Clear, fine audio and outstanding transmitting quality. GREAT purchasing.

73

Oggetto: [POSSIBILE SPAM][TS-520_820_530_830] New 830s Owner - How Do I Determine Wattage Output?

My present to myself for upgrading to General recently was a TS-830s. Everything I read about this rig was outstanding. I have been operating it for about a week now with good results but can't figure out how to tell from the meter how many watts I'm putting out. Can anybody help me out?

Thanks in advance for the assistance.

Kevin - KI4KFS

The multimeter in the radio does not have a watt meter function. You should get a good quality watt meter.

6981. TS-830S Frequency Jump

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-03-21 13:46:13 UTC
From: steveb84us
Topic: 6981 Message: 6981

Hello to all. This is my first post to the group. I was a long time owner of a TS-530S. A few weeks ago, I picked up a nice looking TS-830S. Last week it seems to have developed a problem on warm-up. For the first 5 minutes of warm-up, the frequency jumps up and down rapidly about as much as a 1.5 kc. After that, the frequency stability is rock solid. Is this something typical or the sign of worse things to come? Any things to look for to remedy the problem?

Thanks,

Steve

Tighten down the mounting screws on the low voltage regulator board. Even
better, put star washers on the screws under the board.

Steve,

This was the subject of a Kenwood Service Bulletin ASB0840.

http://ham.connect.fi/tekniikka/kenwood/AmateurServiceBulletins/ASB0840.JPG

Bill,

ASB0840 refers specifically to the TS830. However, ASB0024 deals with a
variety of problems on the TS820, one of which is frequency instability
(item 14 see
http://ham.connect.fi/tekniikka/kenwood/AmateurServiceBulletins/ASB0024B.JPG).

There are 9 Service Bulletins for the 820/820S.

I have a 820m which i have no history on and it has obviously had some heavy use . It came to me in a trade as i have a 520 and thought it would have a use for spares. However as the receiver works well i decided to have a look at the no tx fault.As i could hear the tx at low level on another Rx I checked all voltages around pa ht etc all appear ok but no bias . I removed the pa pcb and all 4 of the cathode resistors are well and truly burnt [all o/c] Look original! have replaced these and will refit board latter . What is probable cause off failure? and things to check and watch for when i start up.I have read most things on site/web re 520 series so would welcome any advice I dont want to repeat this failure . BOB G8ACQ ps I have a mains Variac so I could bring up to 240v slowly if this is a advantage.

Shorted tubes often take out the cathode resistors. If you are using the same tubes as when the failure occurred, you may want to check them on a tube tester. A tube tester won't usually tell you much, but it can sometimes catch shorts.

You may want to check the screen resistors on the HV board while you have it apart.. They change value with age and become unsoldered.

BTW was that a typo, I am not sure what an 820 m is.

From: Bill Scurlock
Topic: 6923 Message: 6992

Hi Clint.

I don't have any documentation on the 520, but if it is similar to the 530 and 830, you probably need to perform an alignment on all the coils associated with the variable capacitors that are operated with the Drive control so that they "track" on Rx and Tx. The alignment procedure should be in the manual. After the alignment, you can check out each band again and see if they track between Rx and Tx. Hopefully there is a 520 expert monitoring these comments that could provide you with more specific advice. There are other possible issues that could be involved, but you should do the alignment as a first step. It might be that simple a solution. Good Luck.

Subject: [TS-520_820_530_830] Low receive TS520S once properly tuned up ??

I have this problem with a TS520S, all else seems to
work to specs, proper output, and HV readings.

The positon of the Drive control that results in
the best receive volume & deflection on the meter does
not correspond to the position of the Drive control
when this radio is tuned for maximum output.
So when this radio is all tuned up properly the
receive is down. Anyone have an idea where I should
start to try and find the cause of this problem?
Could it be related to the 12BY7A?

Appreciated any and all suggestions.

73,
Clint - WS1V

6993. Best bang for buck VOM?

Yahoo group: TS-520_820_530_830 (2006)

It's time for me to upgrade the VOM I have been using. I am still using a 1 meg ohm analog VOM, which is still quite useful for testing antenna connections and other light duty stuff.

However I would like to be able to chase blown caps and other somewhat higher ends tasks, without spending any more than I have to, yet not have to do an upgrade later.

Suggestions?

I'm a fan of the old Simpson 260 if you're looking for analog meters. For digital, take a look at sometihng like the 8010A bench meter.

I found both of these on Ebay at cheap prices. They were well used, but work well.

I followed the alignment in the service manual and the Drive tracked
ok - xmt/recv.

Hi Clint

It has been a while since I aligned my TS-520 and I think I ran into a similar problem you did. When I went to screw the covers into place I noticed the coil markings on the bottom cover did not line up with the circuit layout I was given with the radio.
Aligning the coils as per the designations on the cover restored the performance.
Funny thing is, the covers were removed for a transformer transplant, and many days went by and the important details on the cover were conveniently forgotton.
Did you follow the alignment steps from the Service manual and does the coil layout concur with whats on the cover?

Hi Bill,
Appreciate the reply to my inquiry...
I'll have to put this rig on the bench, and tweak the receive, and
hope that corrects the problem.
Othewise this rig put out properly, and it has the original tubes.

73,
Clint

Hi Joan,
Thanks for your reply to my inquiry.
I haven't pulled the cover off this rig yet, but once I get some
spare time I'll put it on the bench and see if I can tweak the
receive.
I'll get back to the group with my findings.

From: Daniel
Topic: 6999 Message: 6999

Hello Folks

I own a TS-520SE. I can switch from 110V to 220V. We have here in switzerland about 230V. Is there a problem if I'm runnig 230V and the switch is at 220V? Should I rewire the transformer?

Any Ideas??

Daniel, HB9DDS

Daniel. I measure 240-242 VAC in my shack and operate my TS520 and TS820 on that voltage. Have also operated both on 120 VAC. I have operated on 240 for five years.

Hello Daniel,

Mine is a TS-530SP has been operated on steady 230V 50 Hz for more than two years - most of the time in stand by (heater off if not on the air), day and night.

I have a mains transient protection (a special VDR device) to protect all electronic eqipment that I suggest all of you to use.

Walt The m series has AM, I belive for europe otherwise same.
Today i exchanged screen resistors as 1 was over 20% high . Tried
set again and the low voltage diodes in bridge started arcing so
Ireplaced these definitely poor joints and overheated in past . The
rx then ok other than s meter [receive]at half scale all time
unless reduce rf gain when as expected it rises. unable to zero with
pot. this is causing a simlar problem when I go to tx as readings
are all starting at half scale.Have you any ideas on s meter my cct
is very small and not clear .Did a Quick tune up all seemed ok
untill I again lost cathode resistors and 1 6146 was red hot other
normal? but no sign off any arcing in valves . Which valve do you
think is faulty /was red taking too much current because other not
working ? I will try 2 new valves when i get the meter correct.
Any Ideas on meter would help thanks BOB G8ACQ

They are adding more it seems like every day...point troll....now that sounds like one I want to let into my computer. Doubleclick has also gotten super aggressive here if you folks have not noticed, while security people that get server ID's to lesser protected groups are just being ignored.

Yahoo we luv ya but when you send us something called troll....it just does not make me think pleasant thoughts about it's purpose.

7005. Re: [TS-520_820_530_830] Power Voltage Question

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-03-24 11:15:59 UTC
From: Walt Breining
Topic: 6999 Message: 7005

In our area, Indiana USA, some of us have been using 235 to 240 volts for our amps and rigs because of better efficiency as opposed to 117V to 120V . It also gives us better regulation since the neutrals are not always the best in our area.

We have found it necessary to set up our rigs for 240 instead of 220. Unless we did this, the tube filament voltage ran high and the 12BY7 would sometimes go intermittently into self oscillation particularly on 15 meters.

This change is easily done. The transformer has two primary windings. They each have taps labeled 0, 100, and 120. In 120, the two 0 and the two 120 taps are wired in parallel. In 220 the two windings are wired in series except that the connection to one winding is to the 100 tap and the other is to the 120 tap. This gives a total of 220 V.

There is a wire that runs from a terminal on the 120 / 220 switch that is activated in the 220 mode and runs to the 100 terminal of one winding. I believe it is a white wire. It should be moved up to the 120 terminal on the same winding. This will now give a total of 240 v.

In the US, we run 235 to 240 V. Since you run 230 V I suppose if your actual voltage is 235 or higher, you should change it to 240 V. If your actual voltage is 120 to 125 you should leave it on 220 V. If it is between 225 and 235 volts, I suppose that it is a toss up.

7006. Power Voltage Question part2

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-03-24 11:18:11 UTC
From: Daniel
Topic: 7006 Message: 7006

Thanks for the replay but I have to more exatly. On the TS-520SE there is a Voltage switch which shows 110V/220V.

Some years ago we have lower voltage in switzerland, about 220V and now about 230V.
When I switch the voltage (switch) at the back of the TS-520SE to 220V, waht happendm when my really voltage inhouse is about 230V? Does the transformer overheat in some days?

In the service manual I have 2 version of the transformer: 110/220V and 220/240V Version. I can rewire the existent 110/220 to 220/240. But before I do that I have to know is it nesessery to do the rewiring!

Daniel , HB9DDS

7007. TS-820s no display, no recieve audio

Yahoo group: TS-520_820_530_830 (2006)

Hi everyone,
Unfortunately I have to blame myself for the damage. I made up a new External VFO cable and mis-wired it. I crossed pin 4 (12VAC) and 6 (9VDC Cal). Rig powered up briefly, with the frequency display wandering and then died.
Now I have no display and no recieve audio. So far I think my problem is in the AF-AVR board. I have 14VDC going in but the 9VDC is at around 6V and won't adjust via VR4. I disconnected all but the AF1 connector to see if the 9V was being pulled down, but that had no effect. If I disconnect the bottom connector from the display 9.000.0 is displayed, the display unit survived. Checking components with a meter I am suspecting Q7 2SA496 is shorted. Any help would be appreciated.

Thanks,

Karl

Hi Karl,

Data on the 2SA496 (Q7) can be found at
http://pdf1.alldatasheet.co.kr/datasheet-pdf/view/87361/TOSHIBA/2SA496.html

This may help you choose an alternative if this part is not available.

7009. How long will it all last? - circuit boards, solder, components, etc

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-03-24 20:38:57 UTC
From: ke9zm
Topic: 7009 Message: 7009

I have three of the Kenwood Hybrids now (520S, 820S, and 830S). I also have a Kenwood TS-440AT and some old consumer stereo equipment from the 1970's.

The Hybrids are now about 25 years old. My Kenwood TS-440AT which I bought new is now 16 years old. The consumer stereo equipment is 30 years old.

When I open up the stereo equipment and look at the boards and the solder the areas around where the solder is is tunring brown. My TS-440AT has an intermittent volume knob, not because I abused it. There were a couple of problems with one of my Hybrids which was fixed simply by unplugging, cleaning, and reattaching a connector. When unplugged, the pins on the board seemed to have corrosion.

The question is: how long will this stuff last? Are there any long term studies on how long traces survive on circuit boards; how long solder remains conductive; how long materials that are not conductive stay non-conductive; now long pins and edge connectors will conduct before corrosion build up and creates an open connection; how long transistors last in an ongoing environment of being heated and cooled.. and the same for any component?

So the question is... , with these Hrbrids, is it "use it or lose it" or if you put one of these radio on the shelf and leave it for another 50 or 100 years, will it still work or do these radios and all electronic die with old age (50yrs, 100yrs, etc)

Any insight appreciated.
Gary

Was talking to some folks about this and here is another path to failure.

I wonder how many component failures are due to a kind of "avalanche" effect of other component failures. For example, some components may change their values over time - electrolytic caps for sure and maybe disc caps after a longer time. What about other discrete components like resistors? What is the affect of time on semiconductors that are exposed to various kinds of heating and cooling cycles? I know that in the case of the the Kenwood TS-440 the factory used a kind of wax or sealer to fix the positoin of cores in an inductor and insulate one component from another. Over time, this became slightly conductive and now this is the cause of various erratic behaviors in the TS-440.

Now add up all these small changes in individual components and think about all the downstream components that are affected by these changes in values. What you could have in a sort of avalanche affect where the failure of a few puts stress on an increasing number of components and so on to some sort of "chain reaction" of failure.

Maybe the message is... "you can't stop the aging".. and maybe "once it starts to go, its all going to go". So use it before its too late.

Hi Gary.

Not sure where you are trying to go with this aging discussion, but there is probably some logic in using electrical equipment on a regular basis as opposed to only using it every year or so. Some people think that it is better to never turn off certain types of equipment - such as power supplies - that are more prone to failure at "turn on" than during operation. For example, I have a couple of 12VDC power supplies that have been turned on for maybe 8-10 years that are used with my 450 Mhz repeater system. But, components do age, and at some point something will fail.

About a year ago I refurbished a 75A-4 and a KWS-1 that were manufactured in 1957. The receiver was still working, but the transmitter had a HV arcing problem. The main task was replacing capacitors that were starting to "leak", or that were in parts of the circuit that would be catastrophic if they failed - such as coupling capacitors from plate to grid, etc. As you pointed out, component values do change with age and require replacement or circuit re-tuning, or both. One "avalanche" type failure that I experienced was a 0.01 ceramic disc that shorted out and caused 3 RF Chokes in a 300VDC circuit to burn up. Since it is not practical to replace all the components in a radio, I think "Murphy" just comes by and "zaps" something every once in a while to keep us on our toes repairing old equipment. Then if we get tired of that, we sell all the old stuff and go buy one of the new fancy rigs - so we can send it back to the manufacturer when it goes broke. There are so many different ways for hams to enjoy their hobby. There is no excuse for getting bored - just different ways to pursue our individual interests.

This is the 3rd group of hams I have found that are really interested in their equipment, and in helping others understand and work on their "stuff". The other 2 reflector groups are Collins and Elecraft. There are probably others out there also that I have not had the occasion to visit. Just enjoy the parts of amateur radio that are fun for you.

From: Peter A Markavage
Topic: 7009 Message: 7017

There's tons of info on circuit board life cycles, aging of materials, transistor aging, etc. all over the internet. Contamination of pin and edge connectors is an ongoing issue unless the equipment is operated in a contamination free environment. 40 and 50 years ago electronic products for business and military were designed with a 20 to 40 year life. In today's world, consumer products are designed with an average life of 5 to 8 years. Materials within the product will generally last a lot longer but the technology moves on. I'm still running a transmitter that was built in 1958 and a receiver that was built in 1947 and they both still work great. My AC-DC 5 tube AM table radio made in 1953, that uses a pc board for all the tubes and components, still works great.
If you put your 820S on the shelf for 75 years, it might take a little effort to get it up and running again.

On Fri, 24 Mar 2006 20:38:57 -0000 "ke9zm" <ke9zm@...> writes:
I have three of the Kenwood Hybrids now (520S, 820S, and 830S). I also have a Kenwood TS-440AT and some old consumer stereo equipment from the 1970's.

The Hybrids are now about 25 years old. My Kenwood TS-440AT which I bought new is now 16 years old. The consumer stereo equipment is 30 years old.

When I open up the stereo equipment and look at the boards and the solder the areas around where the solder is is tunring brown. My TS-440AT has an intermittent volume knob, not because I abused it. There were a couple of problems with one of my Hybrids which was fixed simply by unplugging, cleaning, and reattaching a connector. When unplugged, the pins on the board seemed to have corrosion.

The question is: how long will this stuff last? Are there any long term studies on how long traces survive on circuit boards; how long solder remains conductive; how long materials that are not conductive stay non-conductive; now long pins and edge connectors will conduct before corrosion build up and creates an open connection; how long transistors last in an ongoing environment of being heated and cooled.. and the same for any component?

So the question is... , with these Hrbrids, is it "use it or lose it" or if you put one of these radio on the shelf and leave it for another 50 or 100 years, will it still work or do these radios and all electronic die with old age (50yrs, 100yrs, etc)

Any insight appreciated.
Gary

If you are looking for a digital meter, I have found out (the hard way), that you DO get what you pay for. I had an RSR 926 digital multimeter, rated for 750V on the highest AC range. The input chip blew out measuring just under 600VAC. Other than that, I had good luck with the meter, had ranges for just about anything you could want, and it was fairly reasonably priced too. I think around $80.00. So if you are looking for a so-so meter and don't plan on doing anything with high voltages, this might be one route to go.

After I blew the RSR, I splurged and bought a Fluke model 77 series 3 meter. It is not the fanciest one available, but it is a very good meter. It is a bit more expensive than some of the other brands, I think it was around $150.00-$175.00 or so, but in my opinion it is a much superior meter, especially if you like working with older tube type equipment, as both the AC and DC voltage scales go up to 1000v, as opposed to the 750V scale of the RSR and other brand meters.

If I had the money to spend I would buy one of Flukes fancier meters, with the scales for capacitance and all other goodies, but for a basic digital multimeter that should last a long time, the 77 is a good choice.

This is just my 2 cents worth, if any of you disagree, please speak up!

I looked in the "manuals" folder in "files" of this newsgroup.
Given that this is a newsgroup on the Kenwood Hybrids, some of the
manuals are missing for the "Kenwood Collection" in the files folder

I have a few manuals that are not in there that I could contribute.
I know that folks sell them on e-bay.

Are there any copyright issues with placing PDF's for all the
manuals for the Kenwood Hybrids in the files section?

... or to save space, a file with verified links to the PDF's for a
complete set of manuals...

Hey Guys

This is my first post,

I am in Australia, just about to sit my full call soon and the proud owner of a Kenwood TS 820 (with the digital display, and one digit missing as usual) and a newly purchased TS 520.

Great old radios and good to see so many people both here and Stateside love these old "boatanchors"!

The 520 I have has a few issues I have to sort out, like replacing some missing ferrite colis in the 10 meter section of the RF board etc, the usual things a 30 plus year old radio has, but other than a cracked persepex fixed channel cover, looks nice.

Thanks for letting me on board!

Take care guys.

Check below for many of the manuals users of this group might find useful. I'm sure it's been mentioned before, but since it seems members cannot post to the links section, I'll offer them and hope I'm not being too redundant. I think the reason we don't have more manuals is the limited storage space of the group. The TS-820 manuals are taking up all the space. Maybe the posting member of those can zip them or something to make them smaller?

Anyway, more manuals can be found at these links:

http://www.kg6haf.com/kenwood.html
http://www.n2ckh.com/library.htm
http://www.ham.dmz.ro/kenwood/ts-520se.php (limited access)

Hope that helps.

Hey mod, maybe enable the ability to post these links in the links section? Or offer your best ones there? Seems like that feature is disabled for the users. Thanks!

PS

I took the largest PDF file in the files section, opened it in Adobe Acrobat 6, and reduced file size by about 50% with minimal quality loss.

If the mod, or original posting paryt doesn't have the software capability or inclination, I'd be happy to email you the smaller files or re-post them if room is made. It really would be nice to have as much as we can for all the models for which this group is designed. Who knows how long the links offered in the previous post will be around.

I bought a set on eBay at a good price. I think I got lucky when I paid less than 15 bucks for a mis-matched set of four. Of course, I'm hoping I won't be disappointed if I ever need them!

As an FYI if you do have to replace them, be sure to check out section 6.9 and 6.14 of your 520 operating manual. Kenwood says "matched tubes are not required, however neutralization is required with new tubes".

Not that I've ever had to do that yet, fortunately!

Check out this web-page for other details on these tubes:
http://home.comcast.net/~zcomco/The_6146_Family_of_Tubes_1.htm

Enjoy your rig. 73.

Thanks for the info. I bid on four 6146B tubes on Ebay and paid $20.
Each. Two of them are matched and I have read in the manual where matched
pairs are not necessary. Seller said he had bought an inventory of vintage
tubes all in original boxes. The ones that I got are GE. I have access to
a tube tester and will check them out when they arrive. Don¹t want to find
out later they are no good. I am enjoying this old rig more than the new
ones. Quality of sound is better and quality of construction is at a level
that could not be afforded today.....regards KB2SQY Ron 73

If your voltage seldom goes above 230 volts, leave it as is. If it goes above 235 volts rewire it.

It will NOT cause your transformer to overheat. If it gets near 240 v. You may have your receive go dead but it will come back if you turn the rig off. If your max on the days that it is highest is under 235 volts, leave it alone at 220 V.

7033. Help with restoring a newly aquired TS520

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-03-25 22:15:12 UTC
From: m_m_maxau
Topic: 7033 Message: 7033

Hey guys.

I just got a TS 520 from E bay, needs a few parts (which are rare as anything here in Australia!

I need a meter cover (the perspex is cracked on the one on the radio).

I am missing the knobs for the meter and plate? and the fix channel knob.

I also need the 10 meter crystals (or correct frequency and where to locate them inside the radio)

Last but not least I need the ferrite cores from the tuning coils on the rf Board (antenna, RX etc boards, the 28 meg ones)

Any ideas would be great.

I also have a TS 820, with the digital display that has the second digit gone out completely (e.g reads 2X.4551 etc, any ideas where to look.

Congartulations of a great group. I love these old radios and it is great to see that you all do as well!!!

73's from VK 2 Australia

I pulled this from mods.dk. It seems the 820 display is a common
problem. Hope this helps.

"TS-820 Fix the problem with the display

Here is somthing you can do if your digital display on the kenwood
ts-820 is giving you a problem.............

1. Remove the counter assembly unit from the 820.
2. Remove both circuit boards from the counter assembly (upper and
lower boards).
3. Scrape away the varnish from the corners of the boards where the
interconnecting screwes and spacers hold the boards into the case.
4. Reassemble the counter...."

and

"The upper and lower PCBs are connected with a chassies mounted male
plug. I often get high resistance faults on the pins. The fix is to
clean and re-grease the pins. The DG-1 display is fine for months
afterwards."

Hello, I tried these tubes in my TS-830S and I guess they had a short because they took out the cathode resistors. I was unable to get this company to refund money or replace with another set. The only thing I was told to do was to claim the problem was do to shipping. I just could not do that when I did not know for sure. Anyway be aware that these tubes might be a problem in a TS-830S.

I too have used this vendor..got a good deal on solid performing 6146s.. and if you order from them..be sure to ask for the free baseball cap! (mine helps keep the headset from sliding off from where the hair used to live)

Decent prices and VERY fast delivery, not only on 6146's and 12BY7's..but just about any popular tubes used in Amateur Radio.

Bob,

Got a pair of Chinese 6146Bs for my 530 about 6 years ago and they shorted out as soon as I turned the rig on.

I tried some 6146 tubes made in China and they were to tall to fit in the
TS-830S. Height of the tube was the problem.

7043. TS520SE off eBay, some notes of interest

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-03-26 19:54:31 UTC
From: stevehurstg8lik2003

Hi all,
This is my first post though have been 'lurking' for a while
as the proud owner of a bought from new and still totally pristine
TS530SP in 1984.
Took the plunge a week ago and bought a TS520SE on ebay from a radio
amateur in the UK for the eventual price of £117 or I guess quite a
bit under the $200 mark.
It was delivered free to my Dads and on inspection quite OK-the
usual minor rust blemishes on paintwork but barely noticeable.Fan,
dial lights all OK and VFO smmoth to operate.
On powering in RX was it seemed fine, brilliant quality audio and
all bands super-except the S meter was always reading S5 minimum,
more with signal. The resolution for this was simply an S meter cal-
2 pots, one for a zero and the other sensitivity, adjustment
empirically on 20M!Don't know why this had been left as found....
On TX when trying to TUNE sometimes nothing indicated on both RF out
and on anode current, other times worked OK but on main RF tune with
the full screen volts the current and RF output started off
normally, drooped to perhaps quarter scale after less than a second
and then sometimes rose to normal, often did not -leaving only the
60ma bias current showing.
Checked the GE 6146B finals by winding up the bias and could get 75%
FSD on the current metering plus so very healthy.This was the same
on all bands into a 50 ohm load of course.
Tried swopping the RCA 12BY7A driver with a new GE tube-no
improvement. Next step -as it was common to all the bands was a
tweak of T1 on the carrier board without any test gear but simply
monitoring the TUNE O/P on TX and everything came good! As that was
the only adjustment on that small board I felt much relieved!
But on SSB I then found the MIC gain had to be FSD for a reasonable
O/P with the processor on and stations reported 50HZ hum. Replaced
the ancient MIC with a new Kenwood one and a new 4 pin plug and
sorted! MIC gain setting now circa 10PM...
Really very happy with the gear now and hope any you guys may
purchase can have any problems resolved simply.
Still think of these rigs as being Kenwoods best!

Best 73's + GD DX to all,

Steve G8LIK

7044. TS-820S Display Problem - my sad story and what's inside the counter box...

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-03-26 20:00:53 UTC
From: ke9zm
Topic: 7044 Message: 7044

For all you TS-820S owners with a display problem...

First of all, I want to thank Walt N9WB for all the help he gave me via e-mail exchanges. Walt is extremely knowledgable about these radios and a huge asset to this group. I hope he hangs around this group for a long time.

That said, I have a TS-820S that had a couple of display problems. First, it had a "9"s problem. The second digit would change to a "9" at random times, and then turn back to the correct value. The second problem is that the display would go blank as the radio heated up. When this happended, I could turn the radio off, let it rest for a while (10 min), turn it back on, and the display would work again.

Here is what you can expect if you open up the digital the display unit (metal box with 2 circuit boards inside)...

There are 4 screws that hold the display unit in from the bottom. There is one connector down there and two connectors on the top. One is power and the other goes to the display.

If you have a blank display the easiest thing to do is check the power out from the voltage regulator - that is the board with the heat sink behind the counter box. At the connector you should have 5 and 14 volts. If you have the TS-820S operators guide it will show the pinouts and voltages - its pretty simple to test. You should hope this is the problem as this is the easiest to fix.

That was not my problem, so into the display box. When I opened the box and looked at the circuit board and connectors I was surprised to see the state of this. Where the edge connector was attached to circuit board there was a brown crust all around the solder paths. The soldering on the board was dull and messy looking. Some places did not look like there was enough solder for a good connection. There were a couple of "fixes" on one of the boards - one jumper wire and a capacitor soldered on the underside of one of the two boards.

Here is what I did...

1. With a dental tool I scraped all the brown crystal stuff from around where the edge connectors connect to the circuit board and brushed the remaining stuff away with a tooth brush.
2. Using a 35W soldering pencil reflowed all the solder where the

edge connectors attach to the board
3. Inspected the boards and reflowed/added solder at places that looked bad.
4. Used a pencil eraser to clean all the edge connectors and the connectors that join the two boards.
5. Reassembled the box leaving all the side screws off. I did this in anticipation of opening up the box again. The top screws can secure the box cover and also allow you to take the cover off the unit without removing the box from the radio. If you put the side screws in you cant do this.
6. Mounted the box back in the radio and attached two top connectors and one bottom.

So that's it, then I said a prayer and turned on the radio.
The radio powered up and the display came on.
But after a while, about 1 hr the display went blank

None of what I did above solved the problem. To make a long story short, I did a bunch of experiments.

Bottom line, my display fails due to a heat buildup problem. As long as the display box stays relatively cool the display works great. In the course of my experiments, leaving the metal cover off of the display (counter) unit (metal box) allows enough heat to get off the circuit boards that the problem is gone. But now there is no metal cover on the display counter assembly. Don't know if that is a good idea or not. But it solved the problem. I suspect there is a board component failure that is temp sensitve and having the metal cover on the counter assembly puts it over the edge to failure.

That's my story, and I'm stickin' to it.

A tube tester will test fairly well for shorts. Generally, if they show problems on a tube checker, they ARE bad. If they test good, they might be good.

Also, placing a 100 watt light bulb in series with the AC line when first trying them will reduce if not eliminate damage if they are shorted. Be sure to use the CORRECT FUSE!

Save your power transformer !

Place a 100 watt light bulb in series with the AC mains (120V line in the US) going into the rig.
The bulb will glow bright if there is a short but get dimmer if it is cleared.
This keeps you from frying a good transformer while troubleshooting or going through 30,000 fuses.

I usually purchase a short orange extension cord and one of those rubber Edison base (light bulb) sockets that are rubber coated and have a white and black wire coming from it.

These are used as temporary wiring at construction sites. Ace Hardware and most building supply stores have these. The cost of these two parts won't total more than $5.00. with some creative shopping.

Open the orange jacket at a point a few feet from the female plug to expose the White, Green, and black wire. Cut the black wire only.

Connect the black wire from the Edison socket to the black wire that leads to the male end.
Connect the white wire from the Edison socket to the black wire that leads to the female end.
I usually use a 100 watt bulb. This limits the AC current to below 1.2 amps.

Use this for testing or burning in a rig that has been in storage. Also useful when first trying a set of 6JS6 or 6146 tubes in the event that they are shorted.

With a rig that has a short across the transformer
secondary, a possible shorted diode or capacitor or shorted tube, the potential for frying the transformer while troubleshooting is great. I have seen many rigs damaged needlessly this way.
If the bulb glows bright, there is a short.
If it is dim, there is no short.
The bulb will limit the current and keep from frying the transformer.

Do not operate with this. This is for testing only.

Sadly, I have seen many good rigs that originally only had minor problems such as a shorted tube, capacitor or rectifier, turned into parts because the transformer was damaged during troubleshooting.

Please protect your rigs transformer.

Gary,

While you have the cover off maybe you can use a can of circuit cooler to isolate the heat sensitive component. Once it shuts down cooling the defective part should bring it back on.

Finding a replacement part may be a challenge but you may be able to find a compatible substitute.

Good Luck,
Dave

Hey there dave...

Turns out that once the counter fails cooling it alone will not bring it back. To get it back you need to cut the power to the counter assembly and then power it up again. I can do this by pulling the power to the counter assembly by pulling off the connector to the 5v/14v voltage regulator.

If anyone wants to see what is in the counter assembly I put up some hi-res picts of the circuit boards. Someone on that board does not like heat. It does not help that one end of the circuit board is about 1/4 in away from the regulator heatsink. The part of the circuit board closest to the heatsink is farthest from the counter edge connector. To me, those boards look a bit grungy on the solder side.

You can see my TS-820S guts and the detail of the counter assembly opened and disassembled here... (My TS-520S guts are in there too)

http://frrl.dyndns.org/

in the ClassicRadios_Picts folder.

There is other stff on that site. Take what you want. There are some tube manuals in the ClassicRadios_Manuals folder

7050. Danger! High Voltage! Don't let your rig kill you!

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-03-27 11:32:56 UTC

Topic: 7050 Message: 7050

Danger! High Voltage!

Hybrid rigs such as Kenwood TS-520-820-530-830 and Yaesus such as the FT-101 series have high voltages that can be as high as 800 volts in the power supply and final section. These voltages can kill you!

This is actually true of any rig with tube finals. The rigs listed above and many others have this high voltage on the final tubes even during receive. Keep this in mind when working inside these rigs.

After these rigs are turned off, these voltages remain in capacitors and can still harm or kill you. Most of these rigs have bleeder resistors that are SUPPOSED to discharge these capacitors in a short time after the power is off. These are usually of values in the tens or hundreds of thousand ohms and are usually placed across the capacitor to drain it.

Are these working right in your rig? Would you bet your life on it? I wouldn 't.

As a safety precaution, one should ALWAYS discharge these voltages manually before touching anything in the rig.

To do this, unplug the rig and let it set for 3 or 4 minutes. If the bleeder resistors are working, this SHOULD discharge most of the charge. Then using a screwdriver or a good clip lead, short the HV source to the chassis ground. Hold the short there for ten seconds or so.

HV Source:

In the Yaesu FT-101 series, the board PB-1067B has a pin labeled +600 V.
Or the + side of C77 is the same point.
If you cannot find these points then short the top of the plate choke, to ground. The top of the plate choke is the place that feeds the two tube caps by way of parasitic chokes.

With the Kenwoods, on the HV board there is a point labeled + 800. Discharge this point or discharge the top of the plate choke. . The top of the plate choke is the place that feeds the two tube caps by way of parasitic chokes.

There is enough voltage stored up in these capacitors to create a high enough current to stop you heart.

Saged advice.
As a novice I was once bitten by an FT-101. It was a hell of an experience.
All the muscles in my arm and chest were sore and it even changed the tast
in my mouth. I still remeber the experience as if I were watching it rather
than being a part of it. A new respect for electricity.
I was lucky.

Art,
If RF Parts say the tubes were good when shipped, you have no reason to doubt them, either. You will never "know for sure" unless the box is smashed, but especially if it was UPS, rest assured they threw the box around like a badminton birdie. I'd follow RF Parts procedure and file, although I thought the shipper had to initiate the claim, not the recipient.

Walt, very good advice for all of us. When I was checking out my "new" 830, one of the bad components I found was the bleeder resistor in the HV circuit. My voltmeter showed me the problem before my fingers found it. That charged capacitor would have been there waiting for me to touch it for a long time!

What is the probability that rfParts actually tests these tubes
before they ship them? I have no idea, but given what business is,
they probably put them in the box and its your problem.

If you ask for a matched pair, then who does this matching? Seems
to me if you ask for a matched pair someone, somewhere has put them
on some device to match them and therefore verify they work

Whats the deal?

Gary

Hello All,
I have been a customer of RF Parts for over 20 yrs and have never gotten a bad tube,i have purchased over a 100 from them and all are of top quality,one thing I have to is DO NOT BUY THE CHINESE TUBES, the GRIDS FAIL QUICKLY,IN MY EXPERIENCE STICK WITH GE,RCA or SYLVANIA YOU GET WHAT YOU PAY for HERE!I DONT KNOW IF THEIR IS A RUSSIAN TUBE equivelent,but RUSSIAN tubes are excellent,I purchased 2, 8877 SIYLVENTA 8 yrs ago and still going 100% these are in an Alpha 77B,1982 new.I use only RCA-GE 6146 TUBES IN MY TS830S RIGS,AND TS530S.I WOULD FILE an Insurance claim with UPS,they probably played Hockey with the package!
TAKE CARE

I dont know what tubes are in that amp, but I have a Ameritron 811H
with 4 x 811 tubes. The issue with removing tubes is getting the
connector off the top of the tube without breaking it. My Ameritron
(new) 811 arrived with the tubes packed separately. I had to install
them and they warned you about the "high-clamping force" of the
connector on the top of the tube.

The Ameritron folks recommended "The safest way to remove the ceramic
connector is to lift the tube out of the socket. A twisting or
spinning pulling motion can then be applied while holding the ceramic
conector firmly until the tube and connector are separated.

I installed these tubes and those top connector are on there for
sure. On the Hybrids I think the caps are ralatively easy to remove.
But other tube stuff, might not be so easy and the risk is breakage.

Gary
PS Remove power from the amp and let it rest before removing the
tubes... :-)

Hi Paul, I am not sure how RF Parts got into this discussion because the company I was talking about was not RF Parts. I have purchased 6146 tubes from RF Parts and never had any problems at all with service or the tubes.

A Tube type amp will have VERY high voltages, sometimes well over 1000 V! Unplug the amp and let it set for a while. Short the wires to the tube plates (top of tubes) to the chassis ground for a few seconds. It should now be safe to remove the tubes. If you want to be extra cautious, after discharging, check the voltage on them with a volt meter before touching them.

Walt and the group:

A quick reminder for those working around magic bottles, as it was in the old days when folks actually worked on TV sets: Keep one hand in your back pocket when poking around inside.

That will prevent a hand to hand path (through your chest) if you DO happen across the high voltage in a cap or a hot circuit. You might still make contact, but keeping that other hand out of the way will help keep you safe. Long sleeves are another cheap way to not go to ground via your skin!

(Note: Getting a tingle is alright, if its from an attractive person...but beware..your sig other finds out..you might hurt from THAT tingle, too!)

Dear Fellow Group Members...

In light of the recent posts on disappointing tube failures or performance and vendors of questionable service, I can recommend the following vendor as being first class in every respect...I have purchased numerous tubes from Stan, including GE 6146B's via telephone and in-person when he has exhibited his stock at Hamcom in Dallas on several occasions.

You can call him at 561-737-8044 or send him an e-mail at: esrc@...
or visit his site at: home.att.net/~esrc/esrcmain.html

Disclaimer: No connection except to know Stan is a good guy and I have been a satisfied customer for several years.

7064. My experience with RF Parts - 6146W GE "not recommended" for Kenwood....

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-03-28 07:22:34 UTC
From: ke9zm
Topic: 7064 Message: 7064

I called RF parts today and asked them about 6146 tubes. They said that all their tubes were tested and have a 1 yr warranty against defects.

Then they asked me what radio I was going to use this in. I said "Kenwood Hybrid" they told me that the 6146W GE was "not recommended" for Kenwood but the 6146W Sylvania / ECG-Philips were recommended

The GE 6146W are $40/pair and the 6146W Sylvania are $60/pair.

Now that's pretty cool - are the Sylvania recommended since they wanted the $20 difference or was there something more to it than that.

Is it not reasonable to expect that a tube that meets the 6146W spec meets the 6146W spec? If the spec is the spec then what does it matter if its a GE or a Sylvania? If a 6146W is not a 6146W then will the real 6146W please stand up.

Unless they can provide you with facts on what they believe the differences are between these two 6146's that would make a difference in the Kenwood, I would have trouble believing it. I got a pair of GE's in my 830. They've been in there for years.

I just finished re-tubing my TS-520SE and used JAN GE 6146W tubes from K5SVC on eBay. They came packed very well and work just fine - and they were reasonably priced - $15.00 a piece.

I have one last problem that I am trying to figure out on my 830S. In tune mode, I am getting very little to no power out. With the meter switched to IP, I am seeing 10ma at best. Makes it very difficult to peak and dip. I am able to get full power out on all bands after tuning in cw. When I switch the meter to hv, I am seeing 800 volts in cw which sounds normal. However, in tune, I am seeing 950 volts. This sounds very wrong. Should I start by looking at the resistors on the hv board?

Thanks,

Steve - N9SB

7073. Tune up and such things

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-03-28 23:21:27 UTC
From: lajes67
Topic: 7073 Message: 7073

I have been reading a few of the other mesages about not being able to see things when tuning up and other things. I simply post this and hope it will be a help to others. Years ago, when I first got my license, I built, among other things, a Heathkit "Cantenna" dummy load. Over the years, no matter where I had my shack located, it just sat there, on the floor, behind whatever I had my radio sitting on, out of sight but never out of mind as I always tuned my TS530S up into it before I put it on the air. A few years back I noticed that I was unable to really tune the radio up and get any indications that matched what the manual said. After one long session on PSK I noticed one of those smells that says "somethings getting hot", the back area of the 530 was really hot to the touch. I rechecked the SWR into the beam and it wasn't even nice to look at, same thing into the dummy. At this point all kinds of bad visions were going through my mind, coax, beam, radio, just to mention a few things. But for some reason the tune up into the dummy thing kept popping up. I checked the connections and sure enough, the old "open one side" problem, somehow over the years something worked itself loose and a quick hit with the soldering iron fixed the problem, now I was able to tune up correctly into the dummy load, the SWR was where it was suppose to be and I had no further problems on the air.
My point is, just because it says 50 ohm, are you really tuning up into a 50 ohm dummy load or is it something totally different? Just one of those little things that makes it interesting, how's that old saying go "It's the little things in life that are difficult, man can sit on the tip of a mountain but man cannot sit on the tip of a tack".

Try adjusting the bias to 60ma, and see if that makes a difference.

Checked the bias. It was set to 60mA. Still don't understand why
the screen voltage in tune is higher. According to the manual, in
tune, screen voltage is cut 50%. Very confused at the moment.
Thanks for the input.

I use a hundred watt light bulb as a dummy load. It's a pi-network output, 50 ohms, 75 ohms, 92 ohms. It doesn't really care. Don't get hung up on 50 ohm dummy loads. This ain't no solid-state transmitter output.

Tune mode will have higher plate voltage indication; it's in the tune mode. Transmitter RF output should be minimal, around 10 to 30 watts in the tune mode. IP would be minimal; it's in the tune mode. Tune mode is use to peak the driver and set the ALC level and when the meter is in the IP position, helps you to find the initial dip or resonance point. Full output tuning, dip and peak, tune for maximum RF power output, is done in the CW mode.

Check the archives, and also, I believe in the Files folder, the tuning procedures have been documented numerous times.

Steve,

I don't have my '830 service manual at the moment (I'm at work) so I can't give you specific direction but I had a TS-520S with the same problem a couple years ago. It would put our full power in CW but no output in tune.

IIRC it turned out to be the resistor that is used to drop the screen voltage when in the tune mode. Check that section of the switch that selects the tune mode vs the other modes and you should see the resistor. The one in the rig I repaired was open. I don't recall what I determined to be the problem that blew the resistor.

Good luck and please report your findings.

Yes, of course. If the load is not at resonance in tune mode, current and tension can be evertything.
So, to compare HV tension, you should be at resonance and the best way to be sure of that is to make measurements on a 50 ohm dummy load !

If it is an 830, the resistors that affect this are R-15 and R-16 on the rectifier unit board. They are both 56 k. Probably R-15 is fried out. Replace both of them.

As stated below, if you idle current on SSB with the mike gain fully down and the rig keyed is not 60 ma. you should set it for that. Gord has a good point. Walt N9WB

Change the resistors as in my earlier post. Your HV meter is not looking at the screen voltage, it is looking at the plate voltage. With the lower screen voltage, the tubes are not drawing as much current from the HV supply and the plate voltage will go up. It will swamp as you draw more power.

Think about what would happen if you plugged both a lamp and an electric heater into the end of a long extension cord. When the heater turned on, the bulb would dim do to lower voltage when the load increased.

7084. Tuning Up TS-520

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-03-29 10:51:38 UTC
From: unifiedcourt
Topic: 7084 Message: 7084

Would someone run me through the procedure they use for tuning up before transmitting. I do not have a dummy load yet but would also entertain any suggestions for what kind to purchase.
When the TS-520 is turned to the "tune" position I noticed the output is very low, about 10 watts. And when I turn to CW the output is 100 Watts. Transmitting using a tuner does not show anything more than 10 watts output. Ron KB2SQY

I've found the fastest and easiest way to tune up is to start by setting
drive control for max ALC in the tune mode. Then with the meter
set to IP and the load control at minimum, dip the plate current with
the plate knob. Then switch to CW mode and RF output on the meter.
Key the rig and increase the output with load knob (clockwise) then
increase it with plate knob (usually counter-clockwise). Alternate
between load and plate until you have maximum output.
Keep key down time short.
Hope this helps.
Steve W4IMF

Thanks Steve,

This is what I was looking for. Does a dummy load work better or is this procedure sufficient for this radio? Ron KB2SQY

7093. Tune-Up procedure and explanation for tube amps in general

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-03-29 23:05:43 UTC
From: ke9zm
Topic: 7093 Message: 7093

For all the tune-up folks. For the hybrids, follow the basic cookbook instructions in the Kenwood manuals.

Here is a bit more detail of what you are doing and why you are doing it. This applies to tube amps in general. Plus links on how to care for your tubes and other relevant info.

http://www.kk5dr.com/Tuneup.htm

Gary / ke9zm

PS I have read some folks doing tune-up with no load at all. Seems to me that essential equipment for any ham is a tuner and a dummy load. If you have neither, MFJ has a tuner with a built-in 300W dummy load for about $100. It is something you will use all the time and worth the investment over a 100W light bulb.

7094. Re: [TS-520_820_530_830] Re: Digital modes on 830

Ken,
The mike gain controls your output as your soundcard
output goes to the mike input.
I take it u havn't actually
begun running digital modes. Best to do some reading
(back issues of qst, web sites etc.) digital modes are not
a big deal to interface or use some r.s. hardware and a few
resisters are all u need to give it a try. Download multipsk
freeware and away u go. The old rigs may require some
warmup to prevent drift but I use a 530s all the time and
have used a 520 and a tentec scout as well.
good luck

Yahoo! Groups Links

Talk is cheap. Use Yahoo! Messenger to make PC-to-Phone calls. Great rates starting at
1¢/min.

From: james27613
Topic: 7085 Message: 7095

hi ken,

the best way to reduce the power out when using
digital modes in SSB is to use the ALC circuit.

in the file section of the group, look in MODS,
there is a schematic for the ts-520 that can
be used for the ts-530 and 830 series, just
get the DIN connector.

You pass -9v dc to the alc and it will reduce
power out in ssb

using mic gain is not the best way to reduce power out,
it can cause you to have a distorted signal.

73 james ke4drn

I used my 530S for a few years now on PSK, first QSO I had the other station advised me to turn the power way, way down. If you haven't seen it already, PSK looks like "rail road tracks" and the program I was using all you had to do was put the cursor in the middle and away you went. You can tell who is really running "power", everything is wide and in some cases you can see the signal in other parts of the "waterfall display".
I am in no way affiliated with nor do I or will I receive compensation in any form, with that said, I suggest you take a look at the "West Mountain Radio" equipment, the interface is called a "Rigblaster". Everything you need comes in one package and they even throw in a cd with different types of program software and directions on where to find it on the internet, their support is excellent. Should take you about an hour to get on the air and like I said before, all the cables come with whatever you buy and the instructions are easy to follow. It's a good mode, you really don't need more than 10 watts to get out.

For a typical set of 6146 final output tubes, with a pi-network, a 100 watt light bulb will work fine as a power output indicator. It's a nice accessory to have in the shack along with a non-inductive dummy load.

Should work with a dummy load or an antenna. Best to start with the dummy load to prevent interference on the air and then switch to your antenna and touch up the tuning.

7105. Is your QTH in the Portland, Oregon area?

Yahoo group: TS-520_820_530_830 (2006)
Date: 2006-03-31 21:10:35 UTC
From: Ravenswood
Topic: 7105 Message: 7105

Greetings all, and thanks for looking.

My name is Frank, K2NCC, in Hillsboro, Oregon.

I have a Kenwood TS-520. I'm hoping to find someone around my QTH to check out my setup to see what I can do better. For instance, I'd like to verify the rig is tuned right and maybe review my antenna setup.

I bought the 520 in order to get my feet wet, but it seems like I'm barely getting a sweat on them! Some of my QSOs seem fine, but.. well, anyway, I figure we can go over those details later. I have tons of questions and am eager to learn. I do have a radio background from the Army (98H), but to show you how much training we received, I never once heard anything about the danger of RF!

I'm minus the antenna meter (another 200 bucks I'm not quite ready to spend!), so if you have one, please consider bringing it. I think I have everything else. I have a 'scope, multimeter, freq counter, antenna tuner and a dummy load. No CW key, but that too is on my list. (Been eagerly eyeballin' that Schurr Profi 2. Gotta get the antenna meter first tho'.)

Can't offer you any $$$ worthy of your time, but I will offer some good company and some beer and pizza (or a substitute if you prefer).

There's got to be someone willing to hang out some afternoon and play radio with me. I've asked a few others, but no one has stuck to any commitments.

So, if you're in the area, know your way around the Kenwood TS-520 boat anchor, and have a couple of hours to whittle away some afternoon, drop me a line! If you prefer voice, I'll send you my 'phone number and we can co-ordinate.

Even if you don't have the time, maybe you'll know someone who does.

Thanks again to all, and 73.

Frank, K2NCC

Frank,
Sorry, I'm in the beautiful Blue Ridge Mountains of western North Carolina
and can't help out personally. But, if you're looking for an antenna
SWR/power meter, check out eBay. There are usually a bunch available for
very few bucks. I've been using a Radio Shack job for many years that cost
$30 new. Click on the following:
http://cgi.ebay.com/RADIO-SHACK-SWR-POWER-METER-CB-HAM-HF-TUNER_W0QQitemZ9706136842QQcateg
oryZ48701QQssPageNameZWDVWQQrdZ1QQcmdZViewItem
to see what I am using. Right now it is listed at $8.00 with a $5.50
shipping charge.
Hope this helps.

Well, I have a tuner that has power/swr (AT-230). What I'd like to
have and from what I understand, an invaluable tool, is the antenna
analyzer. Something like what's found here: http://tinyurl.com/l25vp

Thanks for the info!

Frank, K2NCC

I agree,

I wouldn't mind adding the WARC bands (even just 1 band would be nice). I tried the RUBE site, but you need to be a member to access the site. Also, does anybody know if these Warc band mods are doable, without sacrificing, any of the bands this fine radio already has?

From: Ellen R
Topic: 7114 Message: 7114

Hi everybody,

I'm sort of an old timer. I've been licensed since Feb. 1978., and have been an extra class since Jan. 1994. Up unitl the early 90s, I used mainly tube & hybrid rigs, because it was all I couuld afford.

Just this last Wednesday, my TS-820 (I didn't want to deal with the display issues the 820S has) I bought from Associated Radio arrived. In the mid 80s, when I was in college I briefly owned a TS-520s, and used to use a TS-830S, at the Univ. of WI club stattion, W9YT.

That 830S was a great rig. Once you got used to tuning up, it only took you about a minute to do it, and you were ready to go. I had a lot of fun with that rig. It was the incentive for me to finally upgrade to General in 1986 (I'd been a Novice since 1978), so I could work 160m. I used it on 15m QRP CW, the WARC bands, and even worked KH6CC (via grayline in mid april 1986) on 160m with it. Recently, I decided that I wouldn't mind having another hybrid rig, to sort of take me back to those days. The TS-830S is starting to get noticed by collectors, which is driving prices for good ones up to more than I really want to spend. But its predecessor, the 820/820S is still a pretty reasonable buy. So I bought one. When I took a look at mine on Wednesday, the front panel was similar enough to the TS-830S I used to use, that I knew I'd be able to operate my 820 in my sleep.

Now my question - I've read that there was a version made for the european market (the TS-820M), that had AM capability (whihc is kind of cool). Is it possible to modify the US spec 820 to have AM capbility, without having to literally tear apart the rig, and installing 820m boards (assuming you can even find them anymore)?

73,
Ellen - AF9J

I tend to work mostly in the 40 meter and some 20 meter. I prefer
`evening' or `late night' bands. Too bad this rig doesn't do 160.

Recently, I've been getting better RX and TX. It seems like a small
spike of 10-15 points on the SF propagation is making a huge
difference. Or, it could be something else. Last night, around
midnight, was my greatest distance covered; KH6FKG in Hawaii, about
2500 miles. I regularly get West Coast stations and some
Arizona/Nevada. Not much else so far. The antenna system is
described a little further down the posting.

Now the setup, I am still green, so correct me anywhere it sounds wrong:

It's a TS-520. With this rig, as I read it on the antenna tuner
(AT-230), on a dummy load, I can output 82 watts on 14.235 and 98
watts on 7.235. To get a steady meter measure, I keyed a constant
tone (from a cw oscillator) into the open mic (Astatic D104).

(I tell ya, it takes four hands to do this or weigh down something.
If there's a better way to do this, let me know!)

Meanwhile, I tweaked the plate current and sometimes the load, until
the meter read the maximum power output I could get. This is assuming
everything else is in place and tuned properly.

I peak at 150 watts in normal use.

The SWR is less than 1.5:1 on everything I've worked so far. Even for
an "automatic antenna tuner" I find myself still constantly tweaking
the R-Tune, X-Tune. Kind of a pain if you have to constantly speak on
the air to tune. If there's an easier way for this too, I'd like to
have it!

Now, the antenna. It's an MFJ 1779B, 80-40 meter SSB Dipole. I have
it cut to 34' feet each side. That seemed to be best for 40 meter and
seems to work for 20. Isn't about 65' the full-wavelength for 40
meters?

Anyway, the antenna is stretched along the property fence, held in place with plastic cable pins, and only about FIVE feet above ground.

I'm told this essentially makes it NVIS. The antenna is straight, horizontal, pointing N/S.

That's the entire antenna system I have. It might be okay for some applications (like skip zone), and I'm not expecting any DX with it. My next antenna `upgrade', which I'm sure could be another forum, is a wire loop around the house eaves. My third, methinks is the Gap Titan DX. Your opinions on any of these?

So, in summary; What's wrong with my picture?

Well, I'm sure everyone's in tears, either from the long email or my humorous antenna, but I do appreciate the help in my call-to-action.

Frank, K2NCC

PS In my nine months as an amateur radio operator, I've quickly learned that the ham radio community tends to attract good people.

Thank you.

Seems like, for a bit more money, the PALSTAR ZM30 Antenna Analyzer is a MUCH better investment. With all the complaints I see about most of MFJ's equipment, I'd rather not even start down that road. Check out the eham reviews for the ZM30 here:
http://www.eham.net/reviews/detail/4782

The manual is here:
http://www.palstar.com/manual_zm30.pdf

If anyone owns one, let us know what you think?

Like I said, the TS-820, not the 830. I did exactly what message 5473 recommends - for a TS-830S, to the 830S we had at W9YT (at the Univ. of WI), back in 1987, so I could get the rig on 12m. The 820 has no band switch positions for the WARC bands. I also don't feel like just about gutting the radio to give it WARC band capability. Nor do I feel like losing any of the traditional 6 ham bands, just to add WARC bands. I was wondering if it was possible to use the AUX switch position for this, or will it only receive WWV in the AUX position. If none of this is possible then, I'll just leave the radio alone.

first inprovement would be to make ur ant. into
an inverted v, find someway to get the center up 15 or 20 ft.
and pull the legs off at a 45 deg. or whatever angle u can get, this will
give u a better takeoff angle for "dx", always a relative term.
Second don't sweat a few or even 20-30w in power. it makes
almost no difference.
Third a 20m dipole made from any copper wire u can find cut
to a 1/4 wave on each end will work better than what u have.
The bigest farce in ham radio in the last 20 years is store bought wire ants.
if u have the space a 1/2 wave dipole will out do any shorted ant.
period. Any of the books on wire ants. will be the best investment u can
make in ham radio.
fourth: get a cheap key or even two wires wired to a plug for the key
input to the rig and closing that will key the xmitter(in the cw mode) and allow u to
tune up, but keep it at abt 10 seconds at a time to save the output
tubes.
fifth, try a little cw in the old novice subbands, lots of guys that send
slow and u can work the world on 20m cw. later.
